EXECUTIVE SUMMARY

This Corrective Action Plan (CAP), prepared by Geosyntec Consultants of NC, P.C. (Geosyntec) for The Chemours Company FC, LLC (Chemours), describes proposed remediation activities to address per- and polyfluoroalkyl substances (PFAS) in groundwater and surface waters at the Chemours Fayetteville Works Site (the Site). This CAP was prepared following North Carolina 2L Rules and Paragraph 16 of the executed Consent Order (CO) among Chemours, the North Carolina Department of Environmental Quality (NCDEQ), and Cape Fear River Watch (CFRW). The corrective actions proposed in this CAP were developed to comply with CO requirements and North Carolina 2L rules and to be protective of human health and the environment.

As summarized below and detailed in the body of the CAP, measures already taken by Chemours have addressed and abated almost entirely discharges of PFAS from Chemours's continuing operations at the Site. The remaining areas of PFAS contamination at the Site and associated discharges are almost entirely the legacy of pre-Chemours operations.

PFAS are an emerging class of contaminants; therefore, the understanding of fate and transport of this contaminant class as well as remedial technologies continue to advance and evolve. As such, remedial processes presented herein are intended to be flexible and adaptive so that new understandings, discoveries and technologies can be incorporated in the future. Further, promulgated toxicity criteria for PFAS are limited. However, based on a provisional hazard characterization predicated on exposure to hexafluoropropylene dimer acid (HFPO-DA), no significant human health hazards or negative impacts to ecological receptors were identified based on the projected concentrations to which relevant receptor populations are assumed to be exposed. Nonetheless, the CAP proposes a robust set of remedial actions that will further reduce offsite PFAS loadings, and thus potential exposure, from the Site.

Since 2017, numerous investigations and assessments focused on PFAS have been completed and reported on. These assessments have characterized the facility, surrounding topography, geology and surface water. These assessments served to identify target media for remediation to address CO requirements.

The Site is an active manufacturing facility and is located approximately 20 miles southeast of the city of Fayetteville along the Bladen-Cumberland county line in North Carolina. The Site is bounded by NC Highway 87 to the west, the Cape Fear River to the east, and on the north and south by forested areas, farmland and private residences. The Site has been active since the 1970s. The manufacturing facilities at the Site sit atop a plateau which leads to a bluff with a 100-foot elevation change to a floodplain area and the Cape Fear River. The Cape Fear River is a water source for a number of communities downstream of the Site. Raw water intakes are located at Bladen Bluffs and Kings Bluff Intake Canals, located approximately 5 miles and 55 miles downstream from the Site, respectively.

Historically there have been three release routes of PFAS from the Site to the environment:

1) emissions to air
2) releases of process water to subsurface soil and groundwater; and
3) releases of process wastewater to surface water (Cape Fear River) via the onsite Wastewater Treatment Plant (WWTP).

These release pathways are now being controlled by Chemours for its operations at the Site, but the releases have resulted in secondary sources of PFAS in the environment to groundwater and surface water receptors. This CAP describes actions to address these secondary, and primarily legacy, sources.

The PFAS that originate from the Site are referred to as Table 3+ PFAS. The Table 3+ analytical method was developed to analyze PFAS specific to the Site that were identified through non-targeted chemical analyses. Currently the Table 3+ method can quantitate for 20 PFAS compounds including HFPO-DA, i.e. "GenX". When examining PFAS at the Site, the sum of these compounds, i.e. total Table 3+ PFAS compounds, is often used to evaluate concentration trends and distributions.

The Table 3+ PFAS compounds are found onsite and offsite. The highest Table 3+ PFAS concentrations (by two to three orders of magnitude - i.e. 100 to 1000 times higher) are found onsite. Onsite the PFAS in many of the wells and surface water drainage features have a PFAS signature indicating the PFAS in these wells or surface water features originated from historical direct releases of process water. Onsite the process water signature is found over an area of approximately one square mile. Offsite Table 3+ PFAS in groundwater have an aerial deposition signature and a much lower and diffuse concentration of PFAS over a much larger area (70+ square miles) than the onsite process water signature. The Cape Fear River as it flows past the Site gains a process water PFAS signature indicating that transport pathways comprised of process water signature PFAS loading dominate the mass loading in the Cape Fear River.

Table 3+ PFAS mass loading to the Cape Fear River has been evaluated by measuring flow and Table 3+ PFAS concentrations in the Cape Fear River and the nine transport pathways that contribute Table 3+ PFAS mass loading to the Cape Fear River. The loading per pathway has been estimated using a Mass Loading Model which has been calibrated and evaluated against observed downstream river PFAS concentrations. Based on mass loading model results, the three pathways presently contributing the most Table

3+ PFAS mass to the Cape Fear River are the onsite groundwater seeps, the Old Outfall 002 and onsite groundwater.

Mass Loading Model Total Table 3+ PFAS including HFPO-DA Contributions per Pathway

Transport Pathway	Total Table 3+ Estimated Loading Percentage per Pathway per Event		
	May 2019 Event	June 2019 Event	Sept. 2019 Event
[1] Upstream River Water and Groundwater	4%	15%	8%
[2] Willis Creek	10%	4%	3%
[3] Aerial Deposition on the River	< 2%	< 2%	< 2%
[4] Outfall 002	4%	7%	4%
[5] Onsite Groundwater	22%	17%	14%
[6] Onsite Groundwater Seeps (Seeps A, B, C, D)	32%	24%	42%
[7] Old Outfall 002	23%	29%	27%
[8] Offsite Adjacent and Downstream Groundwater	< 2%	< 2%	< 2%
[9] Georgia Branch Creek	4%	3%	2%

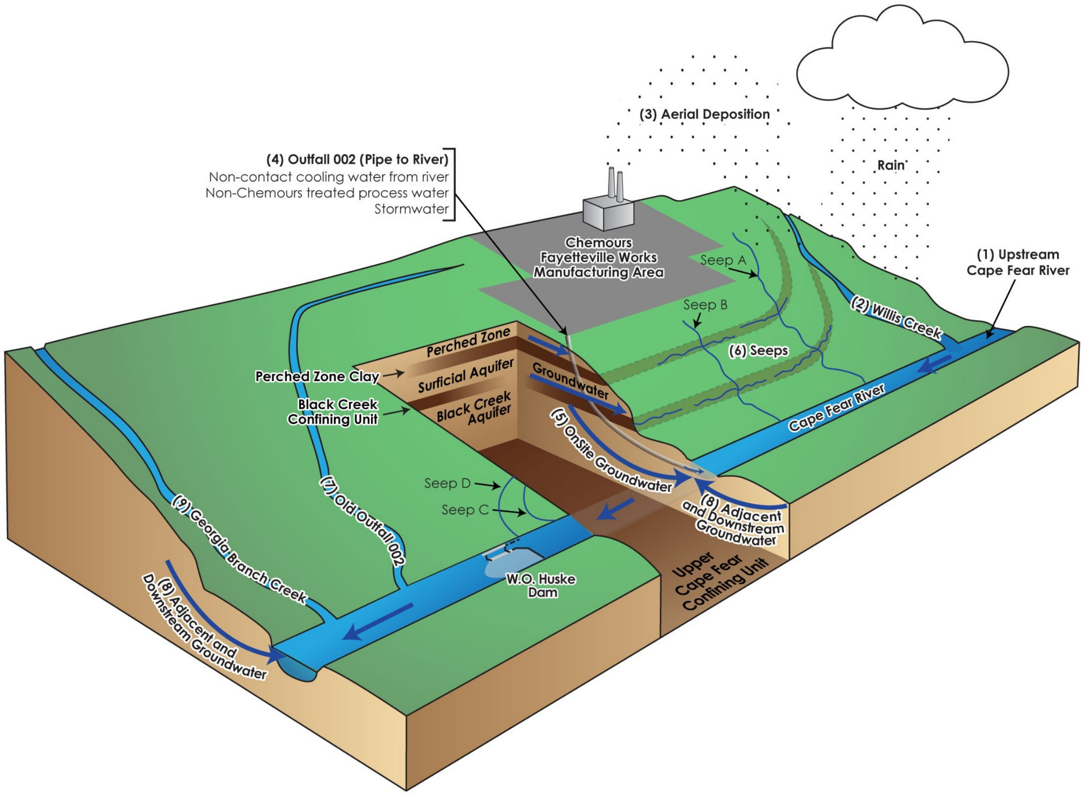

Figure ES1 – Schematic Conceptual Site Model of the Site including geological layers, and PFAS transport pathways

To address PFAS in the environment from past (i.e., legacy) releases, this CAP developed objectives and cleanup goals to guide the evaluation and selection of corrective actions. The CO's remedial and management goals for the Site are:

- Reduce the total loading of PFAS originating from the Site to the Cape Fear River by at least 75 percent (%) from baseline (CO paragraph 16);
- Provide whole building filtration units and reverse osmosis units to qualifying surrounding residents (CO paragraphs 19 and 20);
- Comply with 2L Rules (CO paragraph 16), including following the policy for the intention of the 2L Rules "to maintain and preserve the quality of the groundwaters, prevent and abate pollution and contamination of the water of the

state, protect public health, and permit management of the groundwaters for their best usage by the citizens of North Carolina" (15A NCAC 02L .0103)[1]; and

- Comply with other requirements of the CO.

To support evaluating the need for actions to protect public health and for the actions to reduce exposures, preliminary human health and ecological screening level exposure assessments (HH-SLEA and Ecological SLEA) were completed and are attached to the CAP as Appendices G and H.

The HH-SLEA quantifies exposures of offsite human receptors to released Table 3+ PFAS for several receptor-exposure scenarios and provides a provisional human health hazard characterization for HFPO-DA based on quantified intakes and the North Carolina Department of Health and Human Services (NC DHHS) 2017 draft oral reference dose (RfDo). Calculated hazards for HFPO-DA for all receptor-exposure scenarios evaluated in the HH-SLEA are less than 1 which, as defined by the United States Environmental Protection Agency (USEPA), indicates that adverse effects to human receptors, including sensitive subpopulations, are unlikely. Untreated well water was identified as the primary source of potential PFAS intake and hazard. Furthermore, the HH-SLEA demonstrates that supplying whole building filtration systems and reverse osmosis units for qualifying residents offsite reduces HFPO-DA (and Table 3+ PFAS) intake by over 92%, ensuring human receptor exposures remain below hazard limits for HFPO-DA, based on the NC DHHS draft RfDo. Last, human exposure to PFAS in environmental media will continue to decrease over time as a result of facility air emissions reductions and corrective actions proposed in this CAP. Therefore, based on the HH-SLEA findings, human receptor populations are not being exposed to HFPO-DA above the NC DHHS reference dose by the exposure pathways evaluated. Therefore, the HH-SLEA findings do not necessitate the formation of a cleanup goal.

An Ecological SLEA was also completed to quantify exposure of terrestrial and aquatic ecological receptors to Table 3+ PFAS and evaluate potential hazards related to HFPO-DA. Exposures to Table 3+ PFAS may potentially occur via surface soil, surface water and sediment, along with potential dietary exposures of Table 3+ PFAS that may accumulate in plants, invertebrates and fish. The Ecological SLEA field investigations included collection of onsite and offsite soils, invertebrates and offsite vegetation, and sediment, vegetation, fish and clams from the Cape Fear River for analysis of Table 3+ PFAS. The Ecological SLEA evaluates potential exposure of receptors to Table 3+ PFAS,

[1] The NC DHHS provisional health goal for GenX in drinking water assumes an individual receives 80% of the acceptable dose (i.e., the RfDo) via other sources, such as food. Hence, the provisional health goal was determined such that intake via drinking water does not exceed 20% of the RfDo.

including aquatic life in the Cape Fear River, aquatic dependent wildlife foraging in the Cape Fear River and banks, terrestrial plant and invertebrate communities, and herbivorous, and invertivore wildlife. The Ecological SLEA evaluation indicates there are no adverse effects expected from HFPO-DA exposures. At present, Ecological SLEA findings do not indicate the necessity to develop cleanup goals for HFPO-DA.

Because the results of the HH-SLEA and Ecological SLEA indicate that exposures to HFPO-DA in offsite environmental media do not pose a hazard to human health or the environment, site-specific, risk-based cleanup goals were not developed; rather, cleanup goals are based on CO and 2L rules. The CO requires a minimum of a 75% reduction of total Table 3+ PFAS mass loading originating from the facility to the Cape Fear River. For corrective action under 2L rules when no groundwater standard exists, groundwater must, to the extent technologically and economically feasible, be restored to practical quantitation limits (PQLs) except as otherwise provided in the rules. At present, restoring groundwater to PQLs onsite or offsite is technologically and economically infeasible.

The technical and economic infeasibility to remediate to PQLs is driven by two factors, (a) the area over which the PFAS are detected and (b) the lack of remedial technologies that are effective over large areas and effectively destroy PFAS mass in-situ at a technically achievable and affordable scale. To date, Table 3+ PFAS have been detected over an area of 70+ square miles (over 45,000 acres). The size of the area encompasses thousands of private land parcels and any remedial construction activities using currently available remedial technologies (excavation and groundwater extraction) would be very disruptive to the local community and this disruption would continue for a lengthy period of time. Any remedy which in principle could help make progress towards PQLs over this large area would cost in the billions to tens of billions of dollars. In addition, this hypothetical offsite remedy is unnecessary based on the results of the HH-SLEA and Ecological SLEA; the remedy would result in significant disruption and cost and would result in no meaningful increase in protectiveness. Based on this challenge, in the future NCDEQ and Chemours may need to consider alternate cleanup standards conceived under 15A NCAC 02L .0106 (a) and (i) together and 15A NCAC 02L .0106 (k) individually or risk-based remediation as described by N.C.G.S. § 130A-310.66 et seq.

Therefore, the cleanup goals which drove remedial action evaluation and selection were primarily:

- Achieve a minimum 75% Table 3+ PFAS mass loading reduction to the Cape Fear River;
- For offsite groundwater receptors, provide public water connections or whole building filtration units or reverse osmosis units to qualifying surrounding residents (CO paragraphs 19 and 20);

- For onsite groundwater, mitigate discharge of PFAS with a process water signature to the Cape Fear River and Willis Creek to support achieving the minimum 75% reduction of Table 3+ PFAS mass loading to the Cape Fear River.

Cleanup goals were developed for the Cape Fear River, onsite groundwater seeps, Willis Creek, Georgia Branch Creek and Old Outfall 002 per CO and 2L requirements. These goals are described in the CAP. All these goals support mitigating PFAS loads to the Cape Fear River to help achieve the 75% total Table 3+ PFAS loading reduction to the Cape Fear River.

Based on these goals, and actions proposed in prior CO submittals, a total of nine corrective actions and two interim actions are proposed. The overall schedule for implementation and expected reductions are shown below in Table ES2. These 11 actions include interim and long-term actions that will address at least 95% of the loadings from the onsite groundwater seeps (Seeps A, B, C and D), at least 99% of the loadings from the Old Outfall 002 channel, and significant loading reductions from current Outfall 002.

The CAP also addresses remediation of onsite groundwater and proposes an interim action of extraction of groundwater from existing monitoring wells in the Black Creek Aquifer and treatment prior to discharge. Concurrently, efforts will proceed in developing the detailed design, including collection of extensive pre-design data, for a long-term groundwater containment approach. At this time, the calibrated numerical model indicates the most effective means to mitigate flux of onsite groundwater is the installation of a barrier wall coupled with hydraulic containment of groundwater. The barrier wall component of the remedy would serve to cut off the interface between groundwater and river water and prevent the undesired extraction of river water at the extraction wells.

Extensive investigation, analysis, and numerical model refinement would be required to properly design a remedy of this scale, including but not limited to geotechnical borings, contamination distribution investigations, in-river flux analyses, and pilot testing. It is anticipated that in the course of two years, these activities would allow for model refinement and completion of the design and permitting effort. In the absence of this data, the proposed long-term groundwater remedy is still highly conceptual, and it is not presently possible to conclude with confidence whether this alternative is economically feasible. At the conclusion of the PDI, Chemours will either present a detailed onsite remedial design or a remedial alternative to DEQ for approval based upon achieving at least a 75% Table 3+ PFAS loading reduction and the other CO objectives.

The actions proposed in this Corrective Action Plan will be supported by performance monitoring. Additionally, select onsite and offsite groundwater wells will be monitored at least annually and more frequently for some wells. Last, the CO paragraph 16 requirement for a minimum of a 75% reduction in total Table 3+ PFAS mass loading will be evaluated quarterly. The best available and most representative data will be used to develop the baseline and evaluate reductions performance. These data will include empirically measured flows and concentrations from PFAS transport pathways. These data will include measurements such as flow and concentrations of PFAS in the creeks and in the Cape Fear River in addition to contextual information from groundwater wells including concentrations and groundwater potentiometric surface data. These data will produce direct measurements of PFAS mass loading in multiple pathways and more importantly in the Cape Fear River itself.

Table ES2: Overall Estimated Reductions Plan Schedule and Reductions to Cape Fear River Total Table 3+ PFAS Loadings

Proposed and Provisional Remedial Alternatives	Loading Reduction	Duration (Years)	Year					
			2019	2020	2021	2022	2023	2024
Air Abatement Controls and Thermal Oxidizer[1]	<2%	1	✓					
Conveyance Network Sediment Removal - Outfall 002[2]	NQ[3]	1	✓					
Capture and Treat Old Outfall 002	26%	1						
Terracotta Pipe Replacement - Outfall 002	0.1%	2						
Stormwater Pollution Prevention Plan - Outfall 002	NQ[3]	1						
Groundwater Intrusion Mitigation - Outfall 002	0.7%	2						
Interim Action - CFR Seeps	NQ[3]	2						
Interim Action - Onsite Groundwater	NQ[3]	1						
Targeted Stormwater Control - Outfall 002	1.3%	4						
Ex Situ Capture and Treatment - CFR Seeps[4]	33%	4						
Onsite Groundwater Treatment	18%	5						
Cumulative Estimated Total Table 3+ PFAS River Reductions to River[5]	79%	--	<2%	26%	27%	43%	60%	79%

Notes

- Schedule for multiple alternatives are dependent upon permitting requirements.
- Loading reductions to CFR based on average of May, June, Sep. 2019 data
- Duration listed for implementation

1 - Scheduled implementation is December 31, 2019.
2 - Completed October 2019.
3 - Anticipated reduction from action cannot be quantified at present.
4 - Assumed to be Ex Situ Capture as the permanent remedial alternative for seeps.
5 - Cumulative estimated reductions assumes:
a) that reductions are achieved at the end of the implementation period; and
b) that the time period for contingent actions is not needed.

1 INTRODUCTION

This Corrective Action Plan (CAP) was prepared by Geosyntec Consultants of NC, P.C. (Geosyntec) for The Chemours Company FC, LLC (Chemours) and describes proposed remediation activities to address per- and polyfluoroalkyl substances (PFAS) in groundwater and surface waters at the Chemours Fayetteville Works Site (the Site). This CAP was prepared following North Carolina 2L Rules and Paragraph 16 of the executed Consent Order (CO) among Chemours, the North Carolina Department of Environmental Quality (NCDEQ), and Cape Fear River Watch (CFRW).

The corrective actions proposed in this CAP have been developed to comply with CO requirements and North Carolina 2L Rules, including being protective of human health and the environment. The corrective actions proposed in this CAP will be refined over time as both remedial technologies and understanding advance. PFAS are an emerging class of contaminant, with the Table 3+ PFAS present at the Site from this facility one of the newer sets of PFAS being examined by the remediation industry. The state of knowledge regarding the fate and transport properties, toxicological characteristics, and potential remedial approaches for PFAS and Table 3+ PFAS are continuing to evolve and advance.

The corrective actions have been developed based on multiple investigations and assessments reported since 2017, including multiple actions taken in 2019. These assessments have characterized the facility, an active manufacturing facility, and the surrounding topography, geology, surface water, and groundwater. These assessments enable preparing this CAP by characterizing the Site, identifying which environmental media to target for remediation to reduce human and ecological exposures to PFAS, meet CO requirements, and adapt to Site access conditions such as active equipment, steeply sloping terrain and periodically inundated flood plains.

This CAP is organized into seven sections as follows:

- **Site History and Description** – describes the setting and use of the Site, permitted activities and wastes, and the assessment and regulatory history;
- **Conceptual Site Model** – describes the geology and hydrogeology of the Site, PFAS detected at the Site, the source of the PFAS and PFAS signatures, the distributions and travel times of PFAS in the subsurface and the present mass loading estimate of PFAS to the Cape Fear River;
- **Receptor Information** – describes receptors surrounding the Site and describes the results of both Human Health and Ecological Screening Level Exposure Assessments (SLEAs);

- **Numerical Model Summary** – describes the numerical model used to evaluate groundwater flow at the Site and support onsite groundwater remedy selection and costing;
- **Proposed Corrective Actions** – corrective action objectives, cleanup goals, potential and proposed remedial alternatives, estimated costs, schedules and permitting needs;
- **Performance Monitoring** – describes a baseline monitoring program, remedy performance monitoring, and Cape Fear River PFAS mass loading reductions monitoring;
- **References** – lists documents referenced in this CAP.

Many of the figures and tables referred to in this CAP are from the On and Offsite Assessment report (Geosyntec, 2019a) and herein are referred to by their original number, but with the prefix A, for instance Figure 1-1 becomes Figure A1-1. Tables and figures from the On and Offsite Assessment are provided in Appendix A.

Figures and many tables are embedded for ease of reading, and are ordered sequentially in order of first appearances, i.e. Figure 1, Figure 2, etc. Additional, supporting detail tables are provided in Appendix B and referred to sequentially in order of first mention.

2 SITE HISTORY AND DESCRIPTION

This section provides a brief description of the site location, history of property ownership and use, surrounding land use and adjacent surface water bodies, permitted site activities, assessment and regulatory history. The On and Offsite Assessment Report (Geosyntec 2019a) provides additional details.

2.1 Site Location, Acreage, and Ownership

The Site is located within a 2,177-acre property at 22828 NC Highway 87, approximately 20 miles southeast of the city of Fayetteville along the Bladen-Cumberland county line in North Carolina. Figure A2-1 presents an overview of the Site location. Figure A2-2 presents a regional topographic map and Figure A2-3 presents a higher resolution topographic map of the Site.

The Site property was originally purchased by E.I. du Pont de Nemours and Company (DuPont) in 1970 for production of nylon strapping and elastomeric tape. DuPont sold its Butacite® and SentryGlas® manufacturing units to Kuraray America Inc. (Kuraray) in June 2014 and subsequently spun off its specialty chemicals business to Chemours in July 2015. Chemours and its two tenants, Kuraray and DuPont, currently operate manufacturing areas on the Site, described below.

2.2 Site Description

Presently, the manufacturing area of the Site consists of five production areas (Figure A2-1): Chemours Monomers IXM; Chemours Polymer Processing Aid (PPA) Area; Kuraray Trosifol® Leased Area; Kuraray SentryGlas® Leased Area; and DuPont polyvinyl fluoride (PVF) Leased Area. Chemours also operates the wastewater treatment plant (WWTP) and Power Area at the Site; filtered water and demineralized water are produced in the Power Area. The manufacturing area is approximately 312 acres, as shown in Figure A2-1, the remaining areas are grassy areas, forests and wetlands.

2.3 Adjacent Property, Zoning, and Surrounding Land Uses

The Site is bounded by NC Highway 87 to the west, Cape Fear River to the east, and on the north and south by forested areas, farmland and private residences. Cumberland and Bladen County zoning maps indicate that the surrounding areas are zoned as residential, agricultural, conservation, industrial or commercial.

2.4 Adjacent Surface Water Bodies and Classifications

To the east of the Site is the Cape Fear River. The Cape Fear River and its entire watershed are located in the state of North Carolina (Figure A2-4). The Cape Fear River drains 9,164 square miles and empties into the Atlantic Ocean near the City of Wilmington, North

Carolina. The Site draws water from the Cape Fear River and returns over 95% of this water via Outfall 002 after being used primarily as non-contact cooling water. Two lock and dam systems with United States Geological Survey (USGS) stream gauges are located downstream of the Site: (1) W.O. Huske Lock and Dam, located 0.5 river miles from the Site (USGS 02105500); and (2) Cape Fear Lock and Dam #1, located 55 river miles downstream (USGS 02105769).

The Cape Fear River is a water source for communities downstream of the Site. Raw water intakes are located at Bladen Bluffs and Kings Bluff Intake Canals, located approximately 5 miles and 55 miles downstream from the Site, respectively. These intakes serve as Cape Fear River water intakes for the Lower Cape Fear Water and Sewer Authority, which in turn provides water to Cape Fear Public Utility Authority (CFPUA) and other water providers. Drinking water sourced from the Cape Fear River contains certain chemicals from multiple sources including:

- 1,4-dioxane from industrial activities not related to Chemours;
- trihalomethanes associated with bromide content from other industrial and agricultural sources (NC DWR, 2017) in raw river water,
- pharmaceuticals, personal care products, and endocrine disrupting chemicals primarily from treated municipal waste waters,
- and PFAS from the Site and other sources.

A brief description of these chemicals and their presence in the Cape Fear River was reported previously (Geosyntec, 2018a).

Two tributaries to the Cape Fear River, located to the north and south of the Site, are described in the Seeps and Creeks Investigation Report (Geosyntec, 2019b). To the north of the property is Willis Creek. During the Seeps and Creeks Investigation, Willis Creek was observed to have a flow rate of approximately 2,900 gallons per minute (gpm) in dry weather and 6,500 gpm following significant rainfall. Willis Creek reaches from Highway 87 to the Cape Fear River. To the south of the property is Georgia Branch Creek, which is offsite for its entire course. During the Seeps and Creeks Investigation, Georgia Branch Creek was observed to have flow rates ranging from 2,400 to 2,600 gpm in both wet and dry weather. Georgia Branch Creek runs northwest-southeast beside Highway 87 before turning east towards the Cape Fear River to the south of the Site. These creeks are shown in Figure A2-1.

2.5 Permitted Activities and Permitted Wastes

The Site received its initial Resource Conservation and Recovery Act (RCRA) Permit (NCD047368642) to operate a hazardous waste container storage area and tanks in February 1983, while under DuPont ownership. DuPont submitted an amended Part A application in 1991 to document upgrades to its fluorocarbon waste treatment and tank system. The RCRA Part B permit application submitted in August 1993 identified 71,750 gallons of container storage capacity at the container storage area. Stored waste included characteristic wastes (D001, D002, D003, D007, D009, and D029) and listed wastes (F002, F003, and F005). The Site's RCRA Permit was re-issued in January 1998 and September 2012.

The National Pollutant Discharge Elimination System (NPDES) permit for the Site (NC0003573) includes operations of Site tenants Kuraray and DuPont. There are permit limits for internal Outfall 001, after biological wastewater treatment, that includes the Kuraray and DuPont manufacturing processes, demineralized water neutralized regenerate, sanitary wastewater, and process area stormwater. Effluent limits for Outfall 002, the Site's discharge to the Cape Fear River, include the treated flow from Outfall 001, non-contact cooling water, cooling water discharge from thermal oxidizer cooling tower, stormwater, and boiler condensate blowdown.

In June 2017, Chemours began capturing certain process water from the Monomers IXM area for offsite disposal. Since November 2017, as directed by NCDEQ, all process wastewaters from Chemours's operation have been captured and transported for offsite disposal.

Chemours recently submitted a NPDES permit renewal application for the Site, which contemplates numerous actions, including: (i) continued shipping of Chemours process wastewater from the Monomers IXM and PPA areas offsite, (ii) the intent to build a treatment facility to treat captured baseflow originating from Old Outfall 002, and (iii) a thermal oxidizer with water discharges where no additional PFAS outside of those PFAS present in the river water intake are expected to be present. The recent permit application includes descriptions of recent extensive sampling at the Site for hexafluoropropylene oxide dimer acid (HFPO-DA) and perfluoro-1-methoxyacetic acid (PFMOAA), as well as a number of other PFAS.

On March 14, 2019, Chemours received a Title V Air Quality Permit No. 03735T44 from NCDEQ to construct and operate the emissions sources and associated air pollution control devices(s). This permit authorized Chemours to continue manufacturing operations and install a thermal oxidizer which, along with other air abatement measures, will dramatically reduce aerial PFAS emissions from the Site, with reduction of aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, and expected comparable reductions for other PFAS.

2.6 Prior Site Investigations and Regulatory History

Since 1996, several stages of RCRA Facility Assessments and Investigations have been conducted and are detailed in the RCRA Facility Investigation (Parsons, 2014). The

RCRA Facility Investigation (RFI) process was performed for Site COCs identified in the 2014 RFI including multiple VOCs, metals, other inorganic compounds and perfluorooctanoic acid (PFOA). The RFI process did not include the Site Associated PFAS that are now analyzed by the Table 3+ SOP method; these compounds are listed in Table 2-1. The outcome of the RFI process was the *Corrective Measures Study Work Plan* submitted to NCDEQ on December 2, 2016 (Parsons, 2016). On February 8, 2017, NCDEQ approved Chemours Work Plan for preparing the Final Corrective Measures Study. On July 7, 2017, Chemours requested a delay in the completion of the Corrective Measures Study. The delay was requested as Chemours began voluntary additional sampling and characterization in response to state requests regarding identification and detection of additional PFAS present at the Site.

Since identifying the presence of the PFAS associated with the Site, Chemours has performed multiple investigations and assessments and is continuing to perform assessments that support corrective action for PFAS at the Site. On October 31, 2019, Chemours submitted an updated version of the On and Offsite Assessment report (Geosyntec, 2019a). The tables and figures from this report are attached to the CAP as Appendix A; references to these tables in the text of this CAP report are referred to by the prefix "A" before the table or figure number. The table below list assessments conducted and the second table lists assessments in-progress and planned. Many of these assessment have been required under the CO.

Ongoing PFAS Assessment and Planned Activities

Activity	Description and Status
Offsite Wells	Continued assessment of offsite soil and groundwater in addition to private well data; 20 wells installed. Wells have been redeveloped and resampled.
Private Well Delineation	By August 26, 2020 Chemours is required by CO Paragraph 21 to delineate the extent of private wells offsite with any PFAS on Attachment C of the CO present above 10 nanograms per liter (ng/L) within a quarter mile of other wells with similar detections.
Human Health Screening Level Exposure Assessment	Assessment of human receptor exposures to historically deposited PFAS from the Site. All samples collected and data generated are reported in conjunction with this CAP.
Ecological Screening Level Exposure Assessment	Assessment of ecological exposures to PFAS originating from the Site. Sampling was performed in part with the Human Heath SLEA sampling with dedicated Ecological SLEA sampling and are reported in conjunction with this CAP.
Empirical Laboratory Study	Assessment of Table 3+ PFAS empirical fate and transport characteristics. Portions of the study have begun. Components of assessment are reported in this CAP. The full set of data will be reported in 2020.
Onsite Characterization	Assessment of onsite groundwater levels and concentrations; in 2019, 42 wells installed. Data collected from new wells are reported in the On and Offsite Assessment Report (Geosyntec, 2019a) with redeveloped and resampled well data reported in this CAP.
Sediment Characterization	Chemours submitted the Sediment Characterization plan to NCDEQ on August 21, 2019 and received comments from DEQ dated November 20, 2019.
Quarterly Mass Loading Sampling	Assessment to evaluate mass loading to the Cape Fear River. Sampling and flow gauging performed quarterly in seeps, creeks, the Old Outfall 002,

Activity	Description and Status
	Outfall 002 and groundwater adjacent to surface water.
Numerical Groundwater Model	Quantitative assessment of groundwater at the Site to assess flow to surface water features and assess performance of potential remedies. Results of the numerical modeling are reported as part of this CAP.
Bimonthly PFAS Characterization Sampling	Bimonthly assessment of PFAS concentrations in the Site conveyance network. Data and interpretations are reported quarterly.

3 CONCEPTUAL SITE MODEL

This section describes multiple aspects of the Site including geology, hydrogeology, Table 3+ PFAS, PFAS signatures, distributions, travel times, mass loadings to the Cape Fear River and PFAS reduction actions Chemours has taken to date.

The Site is located in the Coastal Plain of North Carolina and is situated adjacent the Cape Fear River atop a bluff with a 100-foot elevation change to a floodplain area and the Cape Fear River. Willis Creek borders the Site to the north, which flows through an erosional channel and empties into the Cape Fear River. To the south is Georgia Branch Creek which also flows through erosional channels as it empties into the Cape Fear River. Onsite there are groundwater seeps where groundwater is expressed at surface and flows to the Cape Fear River. The largest of these groundwater-fed seeps is the Old Outfall 002, along with four seeps, A, B, C and D located on the bluff slope facing the Cape Fear River.

3.1 Geology and Hydrogeology

The geology at the Site consists of sands and clays. The geology and land use at the Site have influenced the hydrogeology of the Site. The geology of the Site is depicted in a series of cross sections identified in Figure A10-1 and presented in Figures A10-2 through A10-6. The list below describes geological features at Site from surface downward:

- Perched Zone. The Perched Zone is a relatively thin, spatially limited layer of groundwater present in silty sands to a depth of about 20 feet below ground surface (ft bgs) (Figures A10-2 to A10-6). Groundwater in the Perched Zone is recharged through precipitation onsite, and in the past, has received enhanced infiltration through unlined ditches and sedimentation ponds – the sedimentation ponds and the cooling water channel in the Monomers IXM Area have since been lined. Groundwater flows radially away from groundwater mounds in the Perched Zone. This leads to groundwater discharge to the east at seeps on the edge of the bluff, to the south toward the Old Outfall 002 and to the north and to the west downwards through the geological sequence towards the Surficial and Black Creek Aquifers. Based on groundwater extraction rates from the Perched Zone wells MW-24, NAF-03 and NAF-12, the Perched Zone does not produce sufficient or sustainable groundwater yields to be considered an aquifer.
- Perched Clay Unit. The Perched Clay Unit gives rise to the Perched Zone as it presents a barrier to direct downward groundwater infiltration. The Perched Clay is spatially limited at the Site. To the north it pinches out. To the east and south, it outcrops along the bluff face. To the west, it terminates and becomes absent (Figure A10-6). In cross sections through

the Site and observations of grainsizes and lithologic contact elevations from the boring logs, there suggest an erosional feature in the western portion of the geology underlying the manufacturing areas. This erosional surface, described later in this list, is interpreted to have eroded the Perched Clay Unit enabling downward migration of groundwater off the western edge of the Perched Zone.

- Surficial Aquifer. The Surficial Aquifer is an unconfined silty sand aquifer lying atop the Black Creek Confining Unit and is present beneath the Perched Clay Unit. Groundwater in the Surficial Aquifer flows towards the bluff faces at the Site – It flows both north, east and west toward surface water bodies (Willis Creek, Seeps, Old Outfall 002) and discharges into them as seeps. The Surficial Aquifer is interpreted to be in contact with the Black Creek Aquifer in places due to an erosional feature. This feature is labeled on the cross sections and is interpreted to have enabled downward cross formational groundwater flow. Based on North Carolina groundwater classifications (15A NCAC 02L .0201), the Surficial Aquifer is presently classified as a GA groundwater.

- Black Creek Confining Unit. The Black Creek Confining Unit is a layer of silty or sandy clay that separates the Surficial Aquifer from the Black Creek Aquifer. The lithologic contact elevation with the overlying Surficial Aquifer is variable, as is the unit thickness –the Black Creek Confining Unit is interpreted to have been eroded under the western portion of the manufacturing areas at Site. In addition to the Black Creek Confining unit being discontinuous, the potential for downward cross formational flow, also exists based on multiple vertical joints (i.e., fractures in the clay) observed in the Black Creek Confining Unit where it outcrops at the Site.

- Flood Plain Deposits. Surface soils in the flood plain immediately adjacent to the Cape Fear River are comprised of finer grained, likely more recently deposited sediments during river flood stages. These deposits have lower hydraulic conductivity than the Surficial and Black Creek Aquifers. The seeps at the Site cut into Floodplain Deposits as they flow towards the Cape Fear River.

- Black Creek Aquifer. The Black Creek Aquifer is comprised of fine to medium grained sands. The Black Creek Aquifer is in contact with the Surficial Aquifer under the western portion of the manufacturing area at the Site and then is separated from the Surficial Aquifer under most of the manufacturing area by the Black Creek confining unit. The Black Creek

Aquifer directly adjacent to the Cape Fear River is overlain by Flood Plain Deposits and the Black Creek Confining Unit. The Black Creek Aquifer is interpreted to be the only transmissive groundwater zone at Site in direct contact with the Cape Fear River. Groundwater in the Black Creek Aquifer flows from west to east towards the Cape Fear River. Based on North Carolina groundwater classifications (15A NCAC 02L .0201), the Black Creek Aquifer is presently classified as a GA groundwater.

- Upper Cape Fear Confining Unit. The Upper Cape Fear Confining Unit underlies the Black Creek Aquifer. The Upper Cape Fear Confining unit is regionally extensive clay layer which is upwards of 75 feet (ft) thick at the Site and is likely a barrier to downwards groundwater flow. Groundwater levels in the Upper Cape Fear Aquifer measured at North Carolina Division of Water Resources (NC DWR) wells are 80 ft lower than Black Creek Aquifer groundwater levels immediately above the Upper Cape Fear Aquifer. If the two units were in hydraulic connection, they would have similar groundwater elevations. The dissimilarity in water levels for these co-located NC DWR wells demonstrates that the Upper Cape Fear Confining Unit is a barrier to downward flow from the Black Creek Aquifer to the Cape Fear Aquifer.

- Erosional Feature. A paleo-era process appears to have eroded the Perched Clay Unit, portions of the Surficial Aquifer and the Black Creek Confining Unit in the geological sequence under the western portion of the manufacturing area. This erosional feature potentially enables cross formational flow of groundwater from the Perched Zone, through the Surficial Aquifer and into the Black Creek Aquifer. This feature is a likely controlling factor of the distribution of PFAS observed in the Surficial and Black Creek Aquifers at Site. At present there is no direct evidence to confirm this erosional feature does not cut through the Upper Cape Fear Confining Unit.

3.2 Table 3+ PFAS

This section provides a description of the physical and chemical properties of Table 3+ PFAS found at the Site. Pursuant to CO Paragraph 27, Chemours funded a study analyzing the fate and transport characteristics of identified PFAS compounds originating from the Site in air, surface water, and groundwater (Geosyntec, 2019c). This section summarizes the findings of this study and provides descriptions of empirical fate and transport measurements completed to date on Table 3+ PFAS, including values for the octanol-water partition coefficient (K_{ow}), organic carbon-water partition coefficient (K_{oc})

and surface tension of water containing Table 3+ PFAS. These fate and transport parameters enable a more quantitative estimate of transport times in groundwater and estimates of the partitioning between soil and groundwater these PFAS undergo (i.e. where is most of the mass located, sorbed to soils or dissolved in groundwater).

3.2.1 Summary of Fate and Transport Study

PFAS are a group of man-made carbon-based chemicals composed of a fully or partially fluorinated chain of carbon atoms (referred to as a "tail") and a nonfluorinated, polar functional group (referred to as a "head") at one end of the carbon chain. Fluorination of the carbon chain renders it hydrophobic and lipophobic, while the polar head group is hydrophilic (Mueller and Yingling, 2018). Generally, PFAS vapor pressures are low and water solubilities are high. Most PFAS have one or more negatively charged head groups, so they are likely to be relatively mobile in the subsurface due to the affinity of the head group for water molecules (Mueller and Yingling, 2018).

Most Site associated PFAS, i.e. Table 3+ PFAS, are fluoroethers: their structure includes two carbons connected by an oxygen atom to form an ether bond. PFAS with ether bonds are expected to be less volatile and more soluble in water than non-ether PFAS of equivalent chain length due to the polar oxygen atoms included in their structures. Table 3+ PFAS contain at least one polar head group and many contain additional polar head groups. The structural information for the Table 3+ PFAS is provided in Table A4-1. Also, more PFAS originating from the facility may be identified as part of the non-targeted analytical assessment being performed pursuant to paragraph 11(a) of the CO.

Generally, Table 3+ PFAS are expected to be mobile in the environment given the presence of charged head groups and ether bonds, but they will experience some retardation due to sorption to soils. For some Table 3+ PFAS, mobility may be enhanced relative to straight-chain, non-ether PFAS by their branched structure and the presence of two charged head groups. The mobility of the Table 3+ PFAS will be retarded by various chemical processes but will likely have lower retardation than long-chain PFAS without ether bonds. Chemical processes expected to have the most impact on mobility are sorption to naturally occurring organic carbon in soil and, in the unsaturated soil zone, preferential partitioning to the air-water interface.

The tails of PFAS are made primarily of carbon atoms. They tend to be nonpolar and sorb to organic carbon species in soil and sediment (Higgins and Luthy 2006, Guelfo and Higgins, 2013). Because PFAS tails are also lipophobic, sorption to organic carbon tends to be weaker than that of alkanes. The sorption and retardation of PFAS will increase with increasing fluorinated tail length. For a given soil, sediment, or organic carbon type, the structure of the PFAS tail affects its interactions with organic carbon molecules. Branched isomers tend to have lower sorption affinity than linear isomers of equal chain length (Kärrman et al., 2011). Sorption of PFAS to charged particle surfaces in common soils and sediments is expected to be negligible relative to sorption to particulate organic carbon (Higgins and Luthy, 2006).

Current literature indicates that transformation of most PFAS in the environment is negligible. An important observed environmental transformation of PFAS has been the hydrolysis of some polyfluorinated precursors to form perfluorinated compounds (Mueller and Yingling, 2018) and the biotic degradation of trifluoroacetate (e.g., Visscher et al., 1994). Recently, researchers identified an *Acidimicrobium* microbial species that appears capable of defluorinating select PFOA and Perfluorooctane Sulfonate (PFOS) (Huang and Jaffe, 2019). Components of the Table 3+ PFAS that may be amenable to transformation reactions that degrade the tails of these compounds are ether bonds present in 21 of 24 Site associated PFAS, and carbon-hydrogen bonds present in 5 of 24 Site associated PFAS. (e.g., Weber et al., 2017; note, presently Table 3+ can quantitate 20 of the identified 24 PFAS compounds identified at the Site).

3.2.2 Measured K_{ow} and Calculated K_{oc} for Table 3+ Compounds

The process of retardation of organic compounds, including Table 3+ compounds, will influence their fate and transport in the subsurface. Retention in the saturated zone is controlled by sorption to the solid phase of porous media. Sorption by the solid phase is described by the soil-water distribution coefficient (K_d), which is related to K_{oc} by the fraction of organic carbon in the soil. K_{oc} and K_{ow} are often highly correlated. K_{ow} is a standard parameter used for estimating bioconcentration factors. In this section, a summary of log K_{oc} and log K_{ow} measurements or calculations are described along with a discussion of the impact of the values on Table 3+ compounds fate and transport. Details are provided in Appendix C. Other mechanisms of sorption can also include the potential for PFAS, including Table 3+ compounds to bioaccumulate in organisms. Bioaccumulation in potential receptors is discussed in Section 4.

Log K_{ow} measurements were performed using liquid chromatography retention times (OECD, 2004). Retention times for a set of 11 reference compounds with known log K_{ow} values were first determined, and a calibration curve of retention time versus log K_{ow} created. Then, the retention time for each Table 3+ compound was measured, and log K_{ow} calculated using the calibration curve. The measured Table 3+ log K_{ow} values are presented in Table 2.

To calculate K_{oc}, an equation was developed for the relationship between log K_{ow} and log K_{oc} using 20 reference compounds for which both K_{oc} and K_{ow} values were available. Using the measured log K_{ow} values, log K_{oc} values were calculated for Table 3+ compounds (Table 2).

As expected, log K_{ow} and log K_{oc} values are structure dependent where the longer the chain length, the higher the log K_{ow} and log K_{oc} values, indicating higher sorption and retardation. Branched isomers and increasing number of ether bonds results in lower log K_{ow} and log K_{oc} values, indicating lower sorption and retardation.

For comparative purposes, PFOA, a linear C8 PFAS, has log K_{ow} and log K_{oc} values of 5.3 and 2.35 liter per kilogram (L/kg), respectively, while HFPO-DA, a C6 branched PFAS, has log K_{ow} and log K_{oc} values of 4.24 and 1.69 L/kg, respectively. Also by comparison perfluoro-1-butanesulfonic acid (PFBS), a relatively mobile PFAS, has a measured K_{oc} of 1.0 L/kg. The results in Table 2 indicate that all Table 3+ compounds are more mobile and are expected to be less bio-accumulative than PFOA, with the exception of perfluoro-3,5,7,9,11-pentaoxadodecanoic acid (PFO5DA).

Table 2: Table 3+ Measured Log Kow and Calculated Log Koc Values

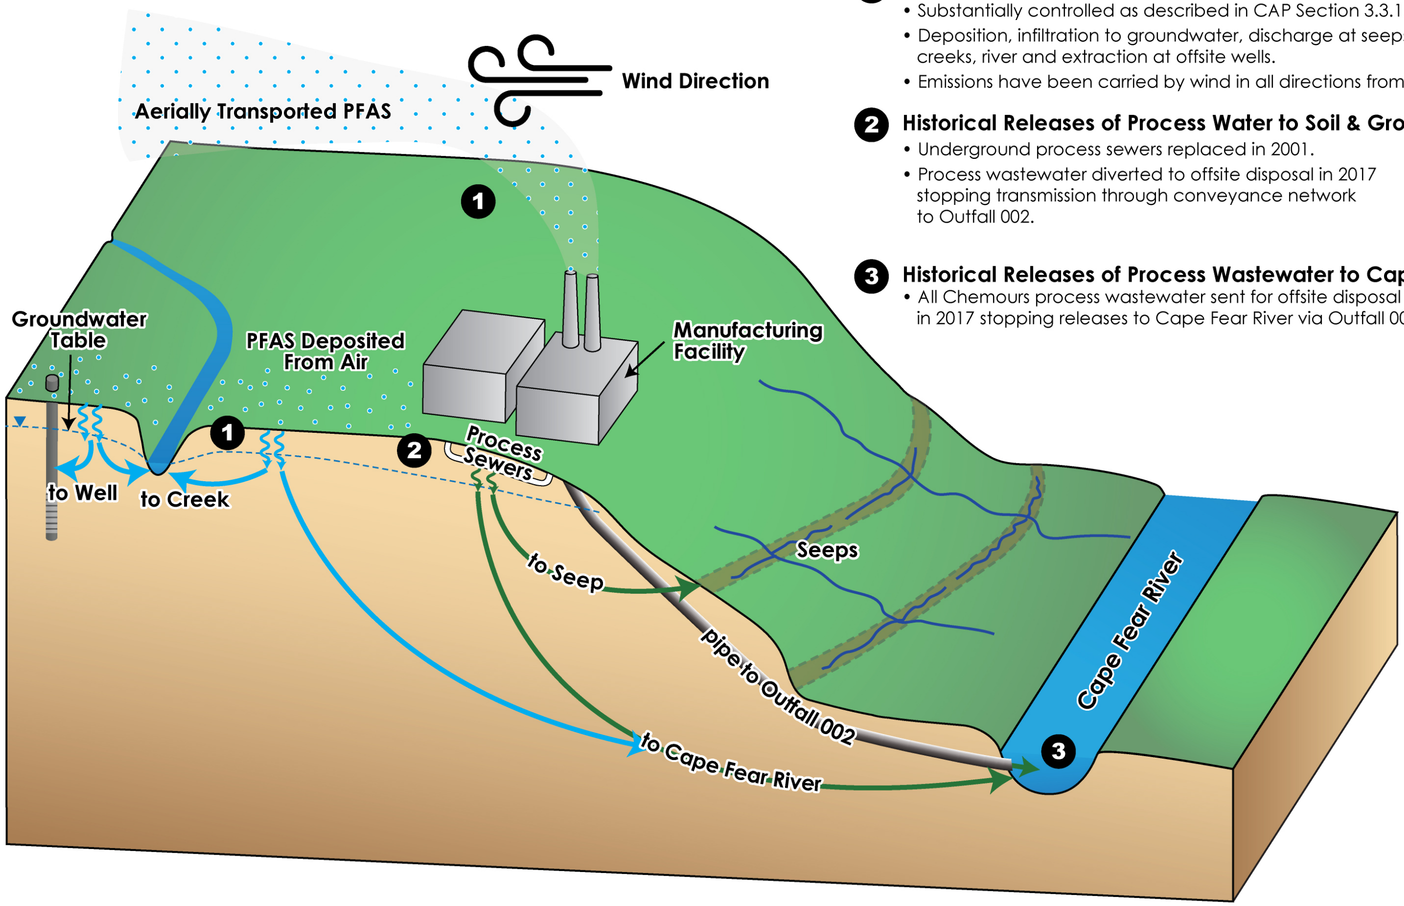
3.3 Site Related PFAS Sources

Fluoroproduct manufacturing at the Site has resulted in three primary PFAS release routes to environmental media: (1) emissions to air, (2) releases of process water to soil and groundwater, and (3) releases of process water to surface water. These releases also resulted in secondary sources of PFAS in the environment to groundwater and surface water receptors. Primary PFAS releases have been identified and are being controlled. The primary and secondary sources are described in the following subsections.



1 Emissions to Air
- Substantially controlled as described in CAP Section 3.3.1.
- Deposition, infiltration to groundwater, discharge at seeps, creeks, river and extraction at offsite wells.
- Emissions have been carried by wind in all directions from Site.

2 Historical Releases of Process Water to Soil & Groundwater
- Underground process sewers replaced in 2001.
- Process wastewater diverted to offsite disposal in 2017 stopping transmission through conveyance network to Outfall 002.

3 Historical Releases of Process Wastewater to Cape Fear River
- All Chemours process wastewater sent for offsite disposal in 2017 stopping releases to Cape Fear River via Outfall 002.

Figure 1: Primary PFAS Sources – Historical Pathways and Present Controls

3.3.1 Emissions to Air

The facility operates multiple permitted air discharge stacks, blowers and vents as part of manufacturing activities. As part of CO compliance, the facility is implementing air control technology improvements that will reduce aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, with expected comparable reductions for other PFAS. Prior to these in-progress reductions and other interim reductions achieved over the past two years, and subject to air abatement systems that had been in place previously, PFAS compounds had been emitted to air and subsequently deposited both onsite and in the area surrounding the Site. The locations of emissions to air and locations of past loading are presented in *Modeling Report: HFPO-DA Atmospheric Deposition and Screening Groundwater Effects* (ERM, 2018) and shown in Figure A4-1. Estimates of past loadings to air and surface water and reductions in loadings achieved are presented in the PFAS Loading Reductions Plan (Geosyntec, 2019d).

3.3.2 Releases of Process Water and Wastewater to Soil and Groundwater

On Site releases of PFAS to soil and groundwater occurred in the manufacturing areas. Known specific release pathways included (i) leakage from historical process water discharge lines, (ii) leakage of combined process water from the terracotta pipe and (iii) a manufacturing (scrubber) upset which occurred in October 2017. Each of these pathways is described below.

Historical process sewer system in Monomers IXM

In 2000, the facility replaced underground piping in the Monomers IXM area that conveyed process waters and wastewaters with aboveground piping (DuPont, 2006). Replacement with aboveground piping enabled routine inspections and the ability to perform more rapid leak detection and repair. The facility has identified one remaining underground pipe connecting the sump at Vinyl Ethers South to the Vinyl Ethers South retention basin. The basin ensures that the Vinyl Ethers South sump does not overflow during heavy rainstorm events.

Terracotta Pipe Leakage

The terracotta pipe was designed to convey wastewater from the various manufacturing areas to the WWTP (Figure A4-1). Prior to June 21, 2017, the facility transmitted PFAS containing process wastewater containing Table 3+ PFAS to the WWTP from the Monomers IXM Area via the terracotta pipe. Leaking of this process water from the terracotta pipe to groundwater is probable and these releases are likely the source of elevated PFAS detections at location PZ-18 and its replacement well, MW-24 (Parsons, 2018a). Chemours no longer transmits process water from the Monomers IXM Area to the WWTP. This process water is sent offsite for disposal. In 2018, Chemours grouted a portion of the terracotta pipe, and by 2021 Chemours and Kuraray plan to fully decommission and replace the terracotta pipe with above-ground piping (Geosyntec, 2019e, f).

October 2017 Scrubber Upset

In October 2017, a scrubber upset occurred in the Vinyl Ethers South area of the Monomers IXM Area (Arnold and Porter, 2017). This release resulted in process water containing PFAS contacting site soils and infrastructure in the Monomers IXM area. Subsequent to this release, Chemours removed soils from this area, replaced some roofing materials and re-lined the cooling water channel with new materials. The scrubber upset resulted in increased HFPO-DA concentrations in the Outfall 002 after rainfall events for up to seven months. As materials were replaced, soils were removed, and the area flushed, observed HFPO-DA concentrations diminished at Outfall 002.

3.3.3 Releases of Process Water to Surface Water

Prior to June 21, 2017, Chemours transmitted PFAS containing process water to the WWTP from the Monomers IXM Area via the terracotta pipe and then to Outfall 002 where this PFAS containing water was discharged to the Cape Fear River. As of November 29, 2017, Chemours diverted Chemours Monomers IXM Area process wastewater flows away from the WWTP and currently containerizes this wastewater for offsite disposal. PPA process water also contains PFAS, and this waste stream has always been collected and sent for offsite disposal since commissioning of the PPA Area.

3.3.4 Secondary Sources

Chemours has taken measures to mitigate releases of PFAS to groundwater, soil, and surface water. Chemours will be implementing air control technology improvements which will reduce aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, with expected comparable reductions for other PFAS. Historical releases resulted in the following secondary sources of PFAS being present in the environment:

- PFAS in unsaturated soils from aerial deposition infiltrating to groundwater. Aerial deposition has resulted in a distributed, non-point source of PFAS in onsite and offsite soils that represent a secondary source to groundwater. Infiltrating rainfall has transported these PFAS downward to groundwater. The currently identified extent of this secondary PFAS source is shown in Figures 4-2A and 4-2B.
- PFAS in soils and groundwater from Site process water releases. Process water leaks in the manufacturing areas resulted in PFAS in Site soil and groundwater. Based on the hydrogeology of the Site, these PFAS are detected in the Perched Zone, Surficial Aquifer, or Black Creek Aquifer and then

migrate towards primarily the Cape Fear River and Old Outfall 002 with some component reaching Willis Creek.

3.4 Monitoring Well Redevelopment and Resampling

Between October 17 and November 8, 2019, a total of 17 wells were redeveloped and 45 wells were resampled (Table 3) based on the recommendations listed below from the Onsite and Offsite Assessment (Geosyntec, 2019a):

- Additional sampling of recently installed wells to evaluate consistency of results;
- Additional development prior to any sampling of wells reporting higher turbidity or perfluoromethoxypropyl carboxylic acid (PMPA) detections below 200 ng/L or non-detect PMPA values with reporting limits above 200 ng/L;

Table 3: Summary of well redevelopment and resampling

Location	No. Wells Redeveloped	No. Wells Resampled
Onsite	11	27
Offsite	6	18
Total	17	45

The list of wells redeveloped and resampled is provided in Appendix B, Table B-1 and Table B-2. Well redevelopment logs/field notes are provided in Appendix B. The results from the resampled wells are provided in the copy of the On and Offsite Assessment Tables A9-3 and A9-4 and in Table B-3.

The total Table 3+ concentrations in resampled wells collected between October 17 and November 8, 2019 were generally within ± 25% range (with some notable exceptions) compared to prior results from June and September 2019 with the following observations:

- Total Table 3+ PFAS concentrations from wells PW-02 and PW-14 were approximately 100 times lower in the resampled results compared to the original samples (15,000,000 to 140,000 ng/L and 18,000,000 to 160,000 ng/L respectively). Resampled total Table 3+ PFAS concentrations for both PW-02 and PW-14 are consistent and within the same order of magnitude as results from nearby onsite wells screened in the Surficial and Black Creek Aquifer, respectively. The concentrations in these wells will continue to be monitored as part of monitoring plan activities described in Section 7.

- For offsite wells where Table 3+ PFAS concentrations were close to detection limits in June, resampled Table 3+ PFAS concentrations were similar or lower in concentrations in October and November. Comparison of Table 3+ PFAS concentrations in offsite wells before and after redevelopment indicate that PMPA had the most notable decrease in concentrations following redevelopment and resampling. PMPA was previously detected in drill water at a concentration of 130 ng/L. Lower concentrations of PMPA in offsite wells may be indicative of well development completion and return to formation water.
- Total Table 3+ PFAS concentrations for wells PIW-7S and PW-06 following redevelopment and resampling were greater than previous results. For example, total Table 3+ PFAS concentrations for PW-06 increased from 3,000 ng/L to 4,400 ng/L while PIW-7S increased from 17,000 ng/L to 54,000 ng/L.

3.5 Southwestern Offsite Seeps

Groundwater seeps are common hydrogeological features in sloping terrain, such as the bluffs found at the Site in the areas around the Site, and much of the Cape Fear River watershed. Onsite there are four seep features with channelized flow that enter the Cape Fear River. In October 2019, ten offsite groundwater seeps - the Lock and Dam Seep and Seeps E to M - were identified on the west bank of the Cape Fear River to the south of the Site. The seeps were identified by performing a visual survey from a boat on the western side of the Cape Fear River between Old Outfall 002 and Georgia Branch Creek. Flow from these seeps ranged from seeping water from an embankment (i.e. trickles) to a visible small stream in one of the seeps. Results from samples collected from the seeps indicate Total Table 3+ PFAS concentrations ranged between 2,600 to 6,800 ng/L. The seven southernmost seeps (G to M) had similar concentrations to the mouth of Georgia Branch Creek sampled in September (2,100 ng/L). However, all offsite seeps had lower concentrations of Total Table 3+ compared to onsite seeps and Old Outfall 002 by one to two orders of magnitude. Similar to Georgia Branch Creek, all of the Southwestern Offsite Seeps had an aerial PFAS deposition signature indicating these PFAS originated from aerial deposition with subsequent infiltration to groundwater and discharge at these seeps.

As these offsite seeps are groundwater fed, their mass loading to the Cape Fear River was included in the offsite adjacent and downstream groundwater transport pathway described in detail in the August 2019 mass loading model report (Geosyntec, 2019) and later in Section 3.10. The offsite adjacent and downstream groundwater pathway was estimated to contribute less than 2% total Table 3+ PFAS loading to the Cape Fear River. Additional details regarding the identification, sampling and photographs of the Southwestern Offsite Seeps are provided in Appendix D.

3.6 PFAS Signatures and Distribution

Releases of PFAS at the Site have created two primary categories of PFAS signatures detected in groundwater and surface water: (1) An aerial deposition PFAS signature from emissions to air and (2) a combined process water PFAS signature from historical releases of process water to soil and groundwater. These primary signature categories are reflected in the PFAS signatures identified in the On and Offsite Assessment report (Geosyntec, 2019a). For this CAP, the data set used to examine PFAS signatures was expanded upon to include offsite private well data and samples from the Cape Fear River, onsite and offsite groundwater seeps, Willis Creek, Georgia Branch Creek, and Old Outfall 002 in addition to the prior use of onsite groundwater results. A hierarchical cluster analysis was performed similarly to the one performed for the On and Offsite Assessment with the exception that this cluster analysis used data for the 11 Table 3+ PFAS data on Attachment C of the CO. Private well data were analyzed for only the Attachment C PFAS and therefore this was the set of Table 3+ PFAS that could facilitate the identification and subsequent comparison of signatures between the samples of private well data and other data sets. The details of the analysis are described Appendix E and the results described below.

3.6.1 Aerially Deposited PFAS Signature and Distribution

The aerially deposited PFAS signature is predominantly found offsite at low concentrations (Figure 2, Table 4). Emissions to air were deposited on surface soils onsite and offsite and have over time infiltrated to groundwater, and in some cases, migrated in groundwater to surface water receptors including the Cape Fear River, Willis Creek and Georgia Branch Creek. Air emission controls will be reducing facility wide emissions of HFPO-DA by 99% compared to 2017 baseline, and are expected to produce a comparable decrease in aerial deposition for other PFAS.

The hierarchical cluster analysis identified two clusters of aerially deposited PFAS signatures. The first cluster (i.e. signature) identified was the 'Aerial – Mixture of PFAS' signature. This signature was a mixture of Table 3+ PFAS where PMPA is commonly the highest concentration with other Table 3+ PFAS (HFPO-DA, perfluoro(3,5-dioxahexanoic) acid [PFO2HxA], perfluoroethoxypropyl carboxylic acid [PEPA] and PFMOAA) detected in a substantial proportion in the samples. Both PMPA and HFPO-DA comprise a substantial proportion of the 'Aerial - mixture of PFAS' signature.

The second signature identified was 'Aerial – Predominant PMPA or HFPO-DA'. Here either PMPA or HFPO-DA dominate the concentration as a proportion of Table 3+ or one of HFPO-DA or PMPA were the only PFAS detected in the sample collected.

Onsite in the Monomers IXM Area, some groundwater wells with high concentrations exhibit a PFAS signature similar to the aerial PFAS signature. These wells are in areas where historically various process sewers were leaking before being replaced. These wells likely have an aerial PFAS signature due to individual historically leaking processes that generated a PFAS distribution similar to the aerial PFAS signature.

3.6.2 Combined Process Water PFAS Signature and Distribution

Among the wells that exhibit the process water PFAS signature, the highest Table 3+ PFAS concentration is PFMOAA, particularly for the combined process water component of the signature. Overall, HFPO-DA, PFMOAA, PFO2HxA, PMPA, and PEPA also comprise a substantial proportion of this signature.

The combined process water PFAS signature is found onsite at high concentrations. As described in the On and Offsite Assessment report (Geosyntec, 2019a), the combined process water signature is associated with release from where various process wastewaters were combined or where PFMOAA dominated the proportion of PFAS present in an individual process water stream. Offsite detections of the combined process wastewater signature were only observed where releases are presently discharging into the Old Outfall 002, the Cape Fear River and Willis Creek (Figure 2, Table 4). Leaking sewers, the terracotta pipe and other potential direct releases of process water onsite lead to infiltration of process water through soil onsite to groundwater with eventual discharge to onsite groundwater seeps, Old Outfall 002, Willis Creek and the Cape Fear River.

3.6.3 Comparison of Aerial vs. Process Water Signatures

Process water signatures are confined to detections onsite in groundwater while aerial signatures are found offsite and onsite (Figure 2 and Table 4). Process water signatures are associated with much higher concentrations over approximately one square mile. Meanwhile, the aerial PFAS signature are diffuse, at lower concentrations over a 70+ square mile area. The Cape Fear River downstream of the Site has a process water signature based on loading to the river primarily coming from pathways with a process water signature (onsite seeps, Old Outfall 002 and onsite groundwater); historical process water releases are estimated to account for between 76% to 86% of the Table 3+ PFAS detected in the Cape Fear River, with the remainder of 14% to 24% coming almost entirely from historical air process releases.

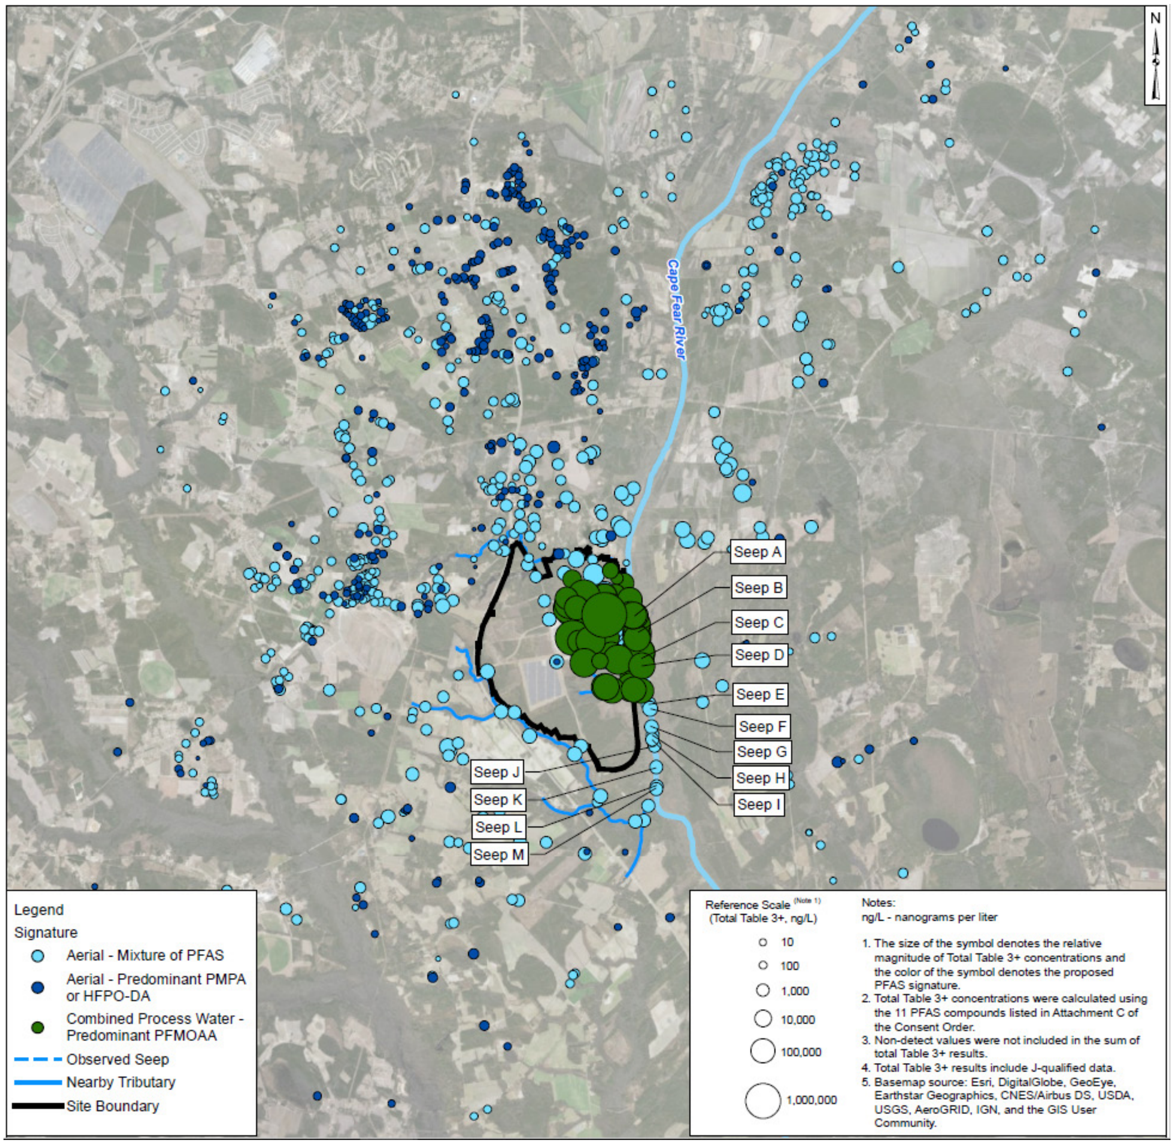


Figure 2: PFAS Signatures by Primary Source

Table 4: PFAS Source Types

Characteristic	Historical Source Type	
	Emissions to Air	**Process Water Releases**
PFAS Signature	Aerial	Process Water
Detected Onsite	Yes	Yes
Detected Offsite	Yes	No
Estimated Area over which Signature is Detected (mi^2)[1]	70+	1
Onsite Total Table 3+ Concentration Range of Detections (ng/L)[2,3]	15 to 13,000	2,900 to 18,000,000
Offsite Total Table 3+ Concentration Range of Detections (ng/L)[4]	10 to 4,500	NA
Percentage Table 3+ Loading to Cape Fear River	14% - 24%	76% - 86%

Notes:

1 - The estimated area with offsite Table 3+ PFAS detections may increase in the future as the offsite private well sampling program continues per CO Paragraph 21 requirements.
2 - For aerially deposited PFAS onsite, the range of detections considered wells located hydraulically upgradient from process water releases; some process water releases had similar PFAS patterns to aerially deposited PFAS. The low and high concentration wells identified were PW-12 and SMW-11, respectively.
3 - For process water PFAS releases onsite the low and high concentrations wells were MW-28 and PIW-14 respectively.
4 - For aerially deposited PFAS off site, low and high concentrations came from private well sampling data. No process water release signatures were detected in offsite groundwater.

3.7 <u>Table 3+ PFAS Mass Distribution</u>

An analysis was performed to determine if Table 3+ PFAS mass was primarily found in the unsaturated zone or in the saturated zone. This analysis was conducted to help evaluate the potential relative benefit between corrective action for unsaturated zone versus saturated zone.

The analysis indicated Table 3+ PFAS mass is predominantly found in the saturated zone at both onsite and offsite locations. This finding was developed by comparing the total mass in a normalized volume (i.e., one cubic meter) of the unsaturated zone (PFAS mass in pore water plus PFAS mass sorbed on unsaturated soil) to the total mass in the same normalized volume (one cubic meter) of the saturated zone (PFAS mass in groundwater plus PFAS mass sorbed on saturated soil) for samples taken from the same location.

The total Table 3+ PFAS mass in a normalized volume of one cubic meter was estimated as follows:

- In the unsaturated zone - the total Table 3+ PFAS mass was estimated using unsaturated soil sample data (unsaturated soil samples are assumed to include both PFAS sorbed on the soil material and PFAS in water content present in the soil sample at the time of collection);
- In the saturated zone - the total Table 3+ PFAS mass was estimated by summing Table 3+ PFAS mass in saturated soil and groundwater. The mass of PFAS in saturated soil was estimated from groundwater data and partitioning calculations. Measured fraction organic carbon (f_{oc}) values and calculated K_{oc} values were used to estimate the mass of PFAS sorbed to soil from which the groundwater sample originated. Values used for f_{oc} were the median value for each lithological unit for both onsite and offsite samples using data presented in the On and Offsite Assessment report (Geosyntec, 2019a). For this assessment, non-detect data were not included.

Results were divided into offsite and onsite locations (Figure 3). The total PFAS mass per cubic meter is higher, by up to almost 4 orders of magnitude (note the vertical axis is logarithmic), in the saturated zone than in the unsaturated zone, except at PW-12 and Cumberland-4S. The detailed calculations behind this assessment are provided in Appendix C. Overall, the results of this assessment indicate that the PFAS mass on and offsite is likely primarily located in the saturated zone.

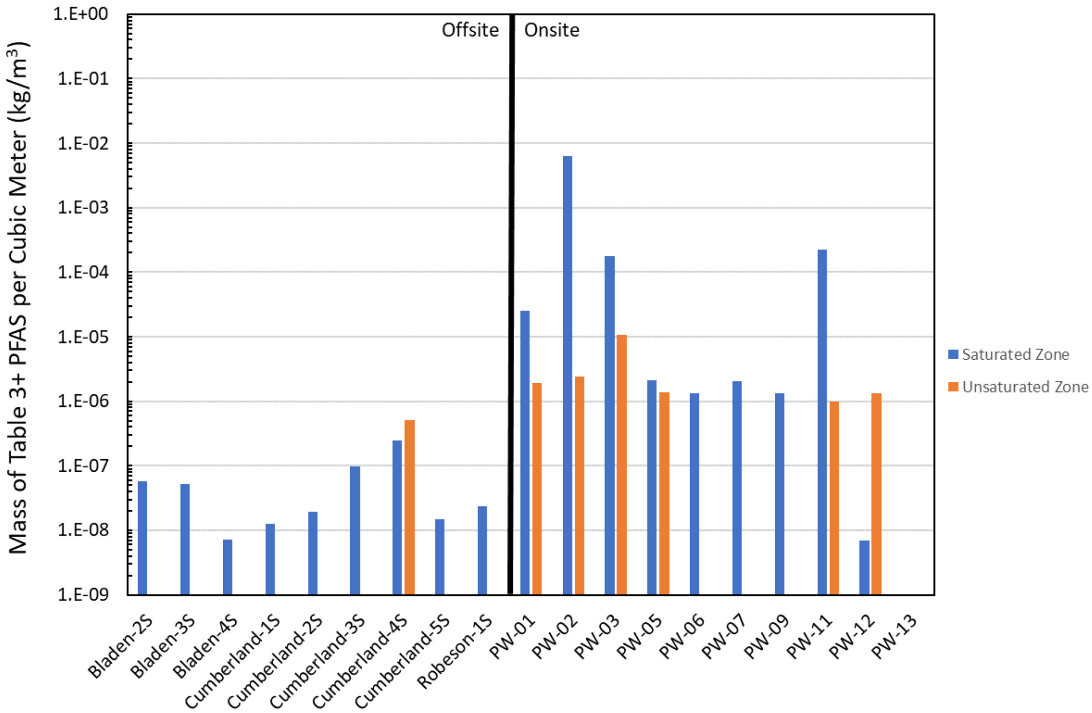

Figure 3: Total PFAS Mass Distribution in a Normalized Volume of the Saturated and Unsaturated Zones

3.8 Table 3+ PFAS Contaminant Retardation

Table 3+ PFAS transport in the subsurface will experience a certain degree of retardation, i.e. slower transport than groundwater as the compounds interact with the aquifer materials. The retardation factor describes how much slower transport will be for a compound compared to groundwater flow. For instance, a compound with a retardation factor of 2 is expected to be transported at only half the rate of groundwater flow (i.e. twice as slow). When combined with groundwater travel time estimates, retardation factors enable estimating travel times for compounds in the subsurface.

Retardation factors were estimated for compounds PFMOAA, PMPA, PEPA, HFPO-DA, PFESA-BP2 and PF5ODA in each of the three saturated zones at Site (Perched Zone, Surficial Aquifer and Black Creek Aquifer). These five compounds spanned the range of estimated K_{oc} values presented in section 3.2.2. Retardation factors were calculated only for saturated zone transport following the work of Brusseau et al., 2019. Chemours is developing and reviewing literature data sets to enable quantitative estimates of unsaturated zone transport retardation factors. The saturated zone retardation factors were calculated as follows:

$$R = 1 + \frac{K_d \rho_b}{\theta_w} = 1 + \frac{K_{oc} f_{oc} \rho_b}{\theta_w}$$

Where:

- R is the retardation factor;
- K_d is the soil-water distribution coefficient;
- K_{oc} is the organic carbon-water distribution coefficient;
- f_{oc} is the fraction of organic carbon in the soil;
- ρ_b is the soil bulk density; and
- θ_w is the volumetric water content (i.e. the fraction of soil porosity filled with water).

The f_{oc} , ρ_b and θ_w used in the calculation for each saturated zone unit are presented below in Table 5. The K_{oc} values used in the calculation and the estimated retardation factors are presented below in Table 6.

Table 5: Soil Property Values

Soil Property	Perched Zone	Surficial Aquifer	Black Creek Aquifer
Median f_{oc}	0.0013	0.0012	0.0034
Median ρ_b (kg/L)	1.45	1.50	1.56
θ_w	100%	100%	100%

The retardation factor estimates suggest in the saturated zone approximately half of the Table 3+ PFAS will experience minimal retardation where travel times will be similar to groundwater travel times; i.e. factors were close to 1. The largest estimated retardation coefficient was for PFO5DA with retardation coefficients calculated to range between 1.7 to 2.9, meaning transport in groundwater will be up to three times as slow as groundwater travel times. The variation in calculated retardation coefficients between aquifer units is primarily a result of differences in fraction of organic carbon values used in the calculations between the different saturated zones. A higher fraction of organic carbon results in a greater degree of retardation; there is more sportive material for the PFAS to interact with during transport. The variation in retardation coefficients between compounds is related to the degree of sorption the compound will experience as described by the K_{oc} value. Overall, the Table 3+ PFAS are estimated to be relatively mobile in saturated zone conditions. These retardation factor estimates can be refined using Site specific measurements of K_{oc} and K_d and evaluating the effects of matrix storage on retardation (i.e. dual phase porosity). These present and future refined estimates of retardation factors can be used to estimate groundwater travel times for flow paths of interest.

Table 6: Calculated Groundwater PFAS Transport Retardation Factors

Compound	**Log K_{oc} (L/kg)**	**Calculated Retardation Factor**		
		Perched Zone	**Surficial Aquifer**	**Black Creek Aquifer**
PFMOAA	0.89	1.0	1.0	1.0
PMPA	1.02	1.0	1.0	1.1
PEPA	1.35	1.0	1.0	1.1
HFPO-DA	1.69	1.1	1.1	1.3
Byproduct 2	1.96	1.2	1.2	1.5
PFO5DA	2.56	1.7	1.6	2.9

3.9 Actions and PFAS Reductions to Date

Actions already implemented by Chemours have reduced yearly HFPO-DA mass loadings from the facility to the environment by at minimum 5,150 pounds per year (lbs/yr) compared to pre-June 2017 emissions and discharges (Geosyntec 2019g). Air emission reductions to date, on an annualized basis for 2019, have resulted in an estimated yearly reduction of 2,150 pounds of HFPO-DA, a greater than 93% reduction. Cessation of Chemours process water discharge to Outfall 002 resulted in at minimum an estimated yearly reduction of 3,000 lbs/yr of HFPO-DA. These actions have reduced HFPO-DA mass loadings, through Outfall 002, by over 99% from June 2017 levels (Geosyntec 2019g). This has resulted in substantial reductions of HFPO-DA to the Cape Fear River. Present estimates of HFPO-DA mass loading to the Cape Fear River from all pathways are between 64 and 129 lbs/yr. This represents a 95% reduction in mass loading to the Cape Fear River from all pathways (Geosyntec 2019g) achieved with remedial measures implemented to date.

Chemours has also implemented multiple actions to further reduce loading of PFAS to the Cape Fear River as outlined in the Reduction Plan (Geosyntec, 2019d).

These reductions will be further enhanced by the operation of the Thermal Oxidizer, which will dramatically reduce aerial PFAS emissions from the Site, with reduction of aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, and expected comparable reductions for other PFAS, and the actions proposed in this plan will further reduce HFPO-DA and other PFAS loadings to the environment.

Actions outlined in this CAP are intended to address PFAS that is present in soil and groundwater from historical operations.

3.10 Present PFAS Mass Loading to the Cape Fear River

Table 3+ PFAS originating from the Site may reach the Cape Fear River via nine possible pathways identified in the Cape Fear Mass Loading Model Report (Geosyntec, 2019g). These pathways are shown in Figure 4 and listed below as follows:

Transport Pathway 1: Upstream Cape Fear River and Groundwater – pathway is comprised of contributions from non-Chemours related PFAS sources on the Cape Fear River and tributaries upstream of the Site, and upstream offsite groundwater with Table 3+ compounds present from aerial deposition

Transport Pathway 2: Willis Creek – Groundwater and stormwater discharge and aerial deposition to Willis Creek and then to the Cape Fear River

Transport Pathway 3: Direct aerial deposition of PFAS on the Cape Fear River;

Transport Pathway 4: Outfall 002 – Comprised of (i) water drawn from the Cape Fear River and used as non-contact cooling water, (ii) treated non-Chemours process water and (iii) Site stormwater which are then discharged through Outfall 002;

Transport Pathway 5: Onsite Groundwater – Direct upwelling of site groundwater to Cape Fear River from Black Creek Aquifer;

Transport Pathway 6: Seeps – Groundwater Seeps (currently identified seeps are A, B, C and D) above the Cape Fear River water level on the bluff face from the facility that discharge into the Cape Fear River;

Transport Pathway 7: Old Outfall 002 – Groundwater discharge to Old Outfall 002 and stormwater runoff flows into the Cape Fear River;

Transport Pathway 8: Adjacent and Downstream Groundwater – Offsite groundwater adjacent and downstream of the Site upwelling to the Cape Fear River; and,

Transport Pathway 9: Georgia Branch Creek – Groundwater, stormwater discharge and aerial deposition to Georgia Branch Creek and then to the Cape Fear River.

Total Table 3+ PFAS loading to the Cape Fear River has been estimated using a combination of measured and estimated data to develop mass loading estimates by pathway. Data inputs for the mass loading model were collected in May, June and September 2019. Results from the May and June sampling events were previously reported in the Cape Fear Mass Loading Model Report (Geosyntec, 2019g). The mass loading model was updated using the same framework as previously described (Geosyntec 2019 g) for the September mass loading sampling event. The analytical data and supporting figures presenting the September data are provided in Appendix B. The mass loading model reporting will be updated in 2020 to incorporate data from the numerical model and be part of the integrated monitoring and assessment activities described in Section 7.

The mass loading model is calibrated and evaluated against observed downstream river PFAS mass loadings. The mass loading model estimates that the Old Outfall 002 and Seeps (Transport Pathways 6 and 7 respectively) have the highest contribution of Table 3+ PFAS mass loading to the Cape Fear River. These two pathways (Transport Pathways 6 and 7) combined are estimated to contribute most of the loading to the Cape Fear River, with totals between 53% and 69% based on May, June and September results (Table 7). Onsite groundwater (Transport Pathway 5) is the next highest mass loading pathway to the Cape Fear River with estimated loading of between 14 and 22% based on May, June and September results.

Geosyntec Consultants of NC, P.C.
NC License No.: C-3500 and C-295

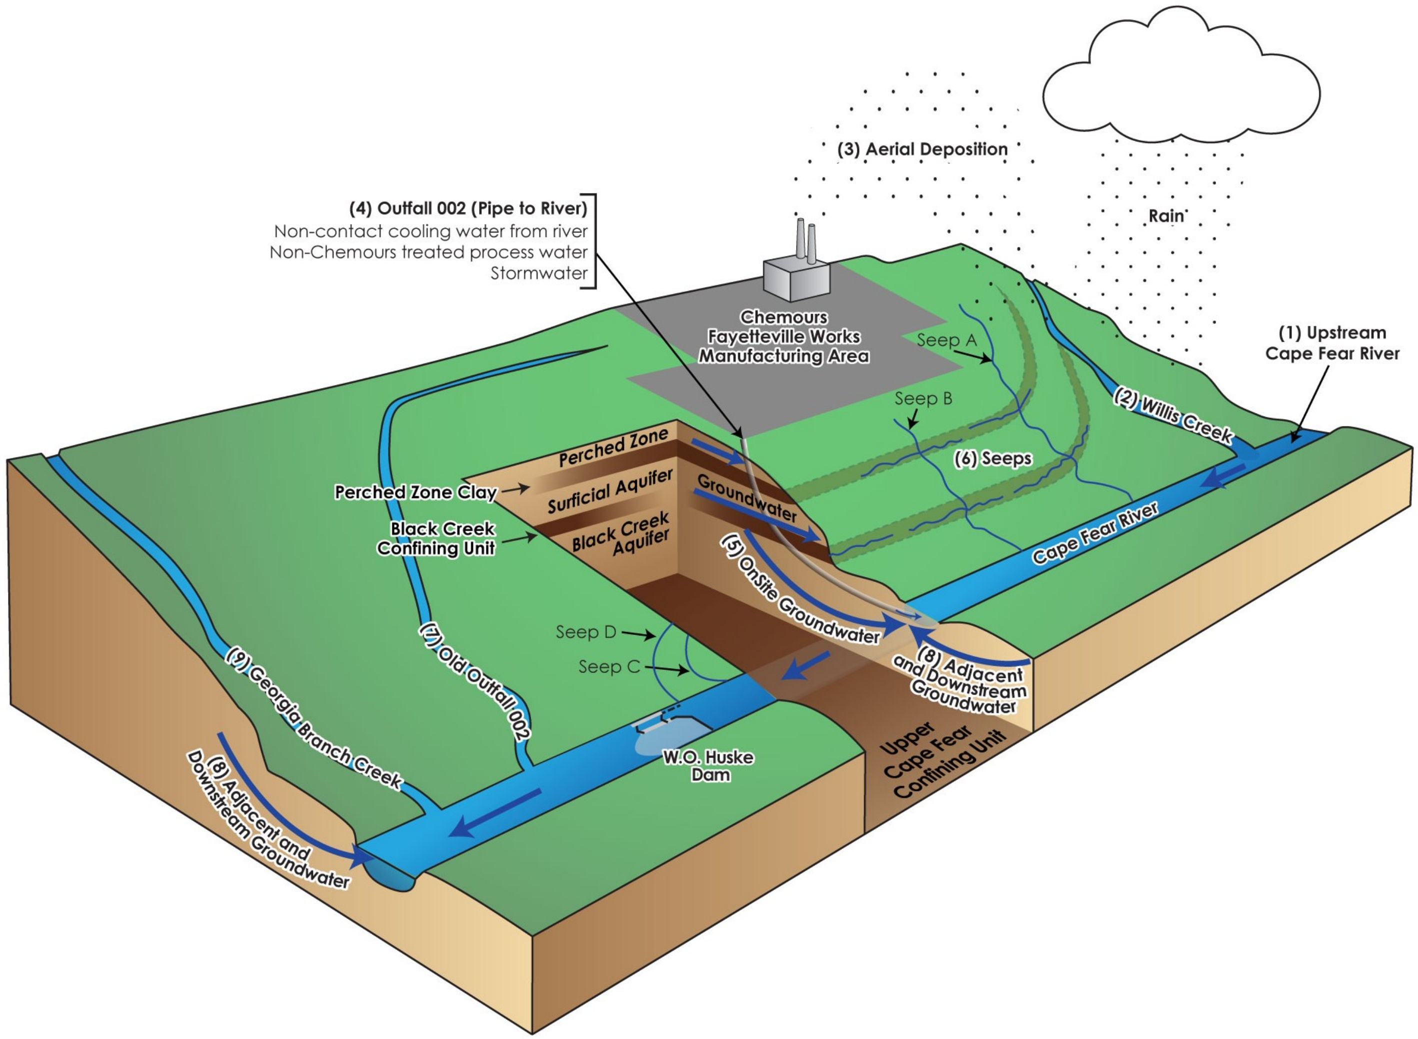

Figure 4: Schematic Conceptual Site Model of the Site Including Geological Layers, and PFAS Transport Pathways

Table 7: Mass Loading Model Total Table 3+ PFAS including HFPO-DA Contributions per Pathway

Pathway	Total Table 3+ Estimated Loading Percentage per Pathway per Event		
	May 2019 Event	Jun. 2019 Event	Sep. 2019 Event
[1] Upstream River Water and Groundwater	4%	15%	8%
[2] Willis Creek	10%	4%	3%
[3] Aerial Deposition on the River	< 2%	< 2%	< 2%
[4] Outfall 002	4%	7%	4%
[5] Onsite Groundwater	22%	17%	14%
[6] Onsite Groundwater Seeps (Seeps A, B, C, D)	32%	24%	42%
[7] Old Outfall 002	23%	29%	27%
[8] Offsite Adjacent and Downstream Groundwater	< 2%	< 2%	< 2%
[9] Georgia Branch Creek	4%	3%	2%

For the Transport Pathways, the loading estimates will vary over time due to a range of potential factors, including but not limited to:

- Detections of PFAS at or near analytical practical quantitation limits have more variability;
- Elevated method reporting limits;
- Standard uncertainty (often ± 20%) in analytical laboratory results;
- Flow rate estimates in the river, seeps, groundwater and creeks are over- or under-predicted compared to actual flow rates.

Chemours will continue to integrate additional sampling data to the mass loading model. Quarterly mass loading sampling will continue to be collected as part monitoring activities described later in Section 7.

4 RECEPTOR INFORMATION

In support of the CAP objectives, Chemours directed Geosyntec to perform a receptor survey as described in the On and Offsite Assessment (Geosyntec, 2019a), a Human Health SLEA, and an Ecological SLEA (SLEA: Screening Level Exposure Assessment). The SLEAs identify potentially complete exposure pathways by which human and ecological receptors may be exposed to PFAS in the environment and use intake models to calculate and rank exposure potential for exposure media such that future evaluations and/or risk management decisions are focused on the most significant contributors of overall human and ecological exposure. The human and ecological SLEAs are provided in Appendices G and H respectively. The following subsections describe the results of a receptor survey and the results from the SLEAs.

4.1 Receptor Survey Results

4.1.1 Wells and Wellhead Protection Areas

As reported in the On and Offsite Assessment (Geosyntec, 2019a), 75 public/community wells and 926 private wells have been identified in the counties surrounding the Site (see Figure A5-1). Community wells are those that serve more than one household. The full extent of offsite PFAS contamination originating from the Site is still being assessed. As such the number of identified private wells is expected to increase. There is limited availability of drilling records including logs and installation depths for many private wells. The geological and hydrogeological settings where these well receptors are present are described, to the extent possible, in Section 3.1. The offsite groundwater monitoring wells installed in August and September 2019 are described in the On and Offsite Assessment Report (Geosyntec, 2019a). Public/community wells identified are listed in Table A5-1, along with their locations, depths, usage, and distance from the Site. Private wells shown on Figure A5-1 are not included in Table A5-1 in order to protect the privacy of well owners. Surrounding property owners are similarly not identified for privacy reasons.

Wellhead protection areas, as defined in the Safe Drinking Water Act: 42 U.S. Code § 300h–7, surrounding the Site are identified in Figure A5-2. According to publicly available data, there is one wellhead protection area in the extent of Figure A5-2, including three municipal water supply wells (PWS ID 03-78-030). Daily water extraction from these wells taken together ranges from 0.18 to 0.30 million gallons per day (MGD). Further details available regarding these wells in the wellhead protection area is provided in Table A5-1.

4.1.2 Surface Water Receptors

Surface waters in the region surrounding the Site include the Cape Fear River, tributaries, ponds, swamps and marshes, and several small streams and ditches. Figure A5-3 identifies named surface water bodies from the USGS National Hydrography Dataset surrounding the Site. Sampling of the Cape Fear River and tributaries to the Cape Fear River has been performed as part of multiple site investigation activities. Sampling of ponds and tissues of fish from the Cape Fear River and one onsite pond has been performed for the Human Health and Ecological SLEAs. These SLEAs are described in the following sub-sections.

4.1.3 Mitigation Measures/Point of Use Treatment

Pursuant to CO Paragraphs 19 to 25 (Compliance Measures - Replacement Drinking Water Supplies), Chemours is implementing a Drinking Water Compliance Plan (Parsons, 2019a). Through this plan, Chemours is providing replacement drinking water to private residents whose drinking water wells are impacted by PFAS listed in Attachment C of the CO. Replacement drinking water is being provided through a range of options depending on the levels of PFAS found as required and defined in CO Paragraphs 19 and 20.

4.2 Human Health SLEA

An Offsite Human Health Screening Level Exposure Assessment (HH-SLEA) was completed to quantify exposure of offsite human receptors to Table 3+ PFAS. The HH-SLEA quantifies exposures of offsite human receptors to released Table 3+ PFAS for several receptor-exposure scenarios and provides a provisional human health hazard characterization for HFPO-DA based on quantified intakes and the North Carolina Department of Health and Human Services (NC DHHS) 2017 draft oral reference dose (RfDo). The HH-SLEA is attached to this document as Appendix F. The subsections below summarize the key components of the HH-SLEA.

Calculated hazards for HFPO-DA for all receptor-exposure scenarios evaluated in the SLEA were less than 1 which, as defined by the United States Environmental Protection Agency (USEPA), indicates adverse effects to human receptors are unlikely, including sensitive subpopulations. Untreated well water was identified as the primary source of potential PFAS intake and hazard. Additionally, when the HH-SLEA accounts for the effectiveness of the Chemours-provided drinking water treatment systems that are currently in-place, PFAS intake via drinking water and associated hazards are substantially reduced and may be as low as zero. While other media were not identified as significantly contributing to overall intake and hazard, human exposure to PFAS in environmental media will continue to decrease over time as a result of Facility air emissions reductions.

4.2.1 Receptors and Exposure Pathways

At the Site, human activities are limited to facilities operations and maintenance, office workers, and environmental monitoring activities. In the area surrounding the Site, there are a wide range of human and land use activities, including private residences, farms, commercial businesses, and recreational areas. Based on the Site setting, the HH-SLEA intake characterization quantifies Table 3+ PFAS intake for the receptor-exposure scenarios identified below. These exposure pathways are assumed to be complete for the purposes of the HH-SLEA but some or all related exposure pathways may be incomplete for an actual offsite receptor. For example, the HH-SLEA assumes gardeners and farmers only consume fruits and vegetables that are homegrown whereas, in reality, most people also (or exclusively) consume store-brought fruits and vegetables grown in a variety of locations. Based on the Site setting, the HH-SLEA intake characterization quantifies Table 3+ PFAS intake for the receptor-exposure scenarios identified below:

1. Residents (adult and child) were assumed to be exposed to surface soil via incidental ingestion; untreated well water as drinking water via ingestion; current conditions well water as drinking water via ingestion; and untreated Cape Fear River surface water from Bladen and Kings Bluffs intakes as drinking water via ingestion.

2. Farmers (adult and child) were assumed to be exposed to surface soil via incidental ingestion; untreated well water as drinking water via ingestion; current conditions well water as drinking water via ingestion; and, aboveground leafy vegetables (e.g., lettuce), aboveground fruits (e.g., tomatoes), and belowground vegetables (e.g., carrots) via ingestion.

3. Gardeners (adult and child) were assumed to be exposed to surface soil via incidental ingestion; untreated well water as drinking water via ingestion; current conditions well water as drinking water via ingestion; and, aboveground leafy vegetables (e.g., lettuce), aboveground fruits (e.g., tomatoes), and belowground vegetables (e.g., carrots) via ingestion.

4. Recreational Canoeists/Swimmers (adult and child) were assumed to be exposed to surface water via incidental ingestion.

5. Recreational Anglers (adult and child) were assumed to be exposed to fish tissue fillets via ingestion.

4.2.2 Intake Characterization

For the purposes of the HH-SLEA, the upland portion of the offsite study area was conceptualized as 12 exposure units (EUs). These EUs were defined by three concentric circles originating from the approximate center-point of the Facility that correspond to radial distances of 2.5, 5, and 10 km; these circles were then bisected north-to-south and east-to-west into four quadrants (see Figure 3 of the HH-SLEA). Five EUs were defined within the Cape Fear River: 10 miles upstream, site-adjacent, 4 miles downstream, 8 miles downstream (Bladen Bluffs), and 55 miles downstream (Kings Bluffs). Finally, an onsite pond and offsite pond were also identified as EUs for evaluation in the SLEA.

Potential PFAS intake from each medium for relevant receptors was estimated using standard regulatory risk assessment equations that combine receptor-specific exposure assumptions recommended by USEPA with media-specific exposure point concentrations (EPCs). Receptor-specific exposure assumptions represent a "reasonable maximum exposure" (RME) scenario and are detailed in Appendix F of the HH-SLEA. Two EPCs were calculated: a central tendency exposure (CTE) EPC represented by the mean concentration and an upper-bound, RME EPC represented by the 95% upper confidence limit on the mean (UCL). If the data did not support calculation of a UCL, the maximum detected concentration was selected as the EPC to support the RME condition.

EPCs for soil, well water, surface water and fish fillets were calculated using empirical data; EPCs for produce were calculated using approved USEPA models. The empirical data used to calculate EPCs in the HH-SLEA are summarized below and presented in Appendix B of the HH-SLEA report.

- *Soil*. The HH-SLEA evaluated offsite surface soil data collected between July and September 2019 from the 12 upland EUs. In each EU, 30 discrete soil aliquots were collected from 0 to 6 inches below ground surface and aggregated into a single composite sample submitted for laboratory analysis that is considered representative of the EU.

- *Well Water*. The HH-SLEA evaluated untreated well water collected between September 2017 and October 2019 from private residences located within the 12 upland EUs. The maximum concentration of each target analyte for each well was included in the HH-SLEA. In many cases, untreated well water is not representative of current drinking water conditions. Therefore, a Current Conditions well water exposure scenario was also quantified, which considers the requirements of the CO for providing replacement drinking water and treatment systems. The Current Conditions intake characterization scenario incorporates an assumption 70 ng/L total PFAS in untreated groundwater to address the scenario where no drinking water treatment may have been required; the Current Conditions hazard characterization incorporates an assumption of 10 ng/L HFPO-DA.

- *Surface Water*. The HH-SLEA evaluated surface water data collected by Chemours from the Cape Fear River between September 2017 and September 2019, from an onsite pond in July 2019, and an offsite pond in September 2019. Additionally, the HH-SLEA evaluated raw surface water data collected by the NC DEQ from the Bladen Bluffs intake point on the Cape Fear River between June and July 2017 and raw surface water data collected by the CFPUA from the Kings Bluffs intake point on the Cape Fear River between September 2018 and October 2019.

- *Fish Tissue*. The HH-SLEA evaluated fish fillet data collected by Chemours from the Cape Fear River and onsite pond between July and September 2019.

4.2.3 Hazard Characterization

The estimated intakes of HFPO-DA were also used to calculate provisional quantitative estimates of potential noncarcinogenic hazard based on the RfDo of 1E-04 milligram per kilogram per day (mg/kg-day) adopted by the NC DHHS. The ratio of intake to the RfDo is defined as the hazard quotient (HQ). An HQ greater than unity (1) was used as the benchmark for identifying potentially unacceptable hazard.

There are other published RfDo values available that may better reflect the toxicological profile of HFPO-DA but a detailed evaluation of the uncertainties associated with these values was outside the scope and objectives of the HH-SLEA. Therefore, the HH-SLEA relied upon the determination from the NC DHHS that, in a regulatory context, the RfDo is protective of human health. Because regulatory risk assessment generally "errs on the side of caution," it must be reiterated that this (or any) RfDo is not predictive of an actual health outcome. As additional toxicological data become available, it may be appropriate to review the hazard characterization results.

4.2.4 HH-SLEA Results

The results of the HH-SLEA intake characterization and provisional hazard characterization are presented in Table 3 of the HH-SLEA and summarized below.

The HH-SLEA identifies untreated well water as the primary source of potential PFAS intake, accounting for over 92% of RME intake for residents, farmers, and gardeners. Additionally, when the HH-SLEA accounted for the effectiveness of the Chemours-provided drinking water treatment systems that are currently in-place, PFAS intake via drinking water was substantially reduced and may be as low as zero. While other media were not identified as significantly contributing to overall intake, human exposure to PFAS in all environmental media will continue to decrease over time as a result of Facility air emissions reductions. As described further below, calculated hazards for HFPO-DA for all receptor-exposure scenarios evaluated in the HH-SLEA were less than 1 which, as defined by USEPA, indicates adverse effects to human receptors are unlikely, including sensitive subpopulations.

Calculated HQs were less than 1 for residents, farmers, and gardeners exposed to soil, produce, and well water in EU1 through EU12, indicating potential HFPO-DA exposure is unlikely to pose a hazard, even in the absence of drinking water treatment. The estimated HQ from untreated well water consumption accounted for 92% or more of total

RME hazard for each receptor. As stated previously, the use of untreated well water to calculate domestic use likely overstates the population's potential exposure, as treatment systems provided by Chemours have reduced PFAS in drinking water to below detection limits. HQ estimates based on an assumption of 10 ng/L of HFPO-DA in drinking water, which is the maximum concentration in well water that would not require a treatment system, range from 0.003 to 0.07 and, hence are more than an order of magnitude below a level of concern (unity or 1). This indicates that there are no hazards to populations of offsite residents, farmers, and gardeners under current conditions, based on HFPO-DA.

Calculated HQs are less than 1 for recreationalists exposed to surface water and fish tissue in the vicinity of the Site, indicating potential HFPO-DA exposure in the Cape Fear River and nearby ponds does not pose an unacceptable hazard to recreationalist populations. The highest HQs (0.08 to 0.1) were driven by consumption of fish from the downstream EU16 at Bladen Bluffs; otherwise, HQs were less than 0.01, indicating there are no hazards to recreationalist populations.

Calculated HQs were less than 1 for domestic use intakes of Cape Fear River untreated surface water from Bladen Bluffs (EU16) and Kings Bluffs (EU17), indicating potential HFPO-DA exposure in surface water does not pose a hazard to residential consumers.

4.2.5 HH-SLEA Uncertainties

Uncertainties are inherent in the process of quantifying exposure (and hazard) due to the use of environmental sampling results, assumptions regarding receptor behavior, and the quantitative representation of chemical toxicity. Therefore, assumptions used in the HH-SLEA aimed to provide additional conservatism where there was significant uncertainty. Key uncertainties identified for the HH-SLEA are summarized below and a more comprehensive list is provided in the HH-SLEA report.

- Toxicity Data. The SLEA provisional hazard characterization is based on the HFPO-DA RfDo of 1E-04 mg/kg-day adopted by the NC DHHS, which is predicated on liver toxicity endpoints from two subchronic studies in mice. There is inherent uncertainty in the use of animal toxicity data to characterize potential human health hazards and the RfDo could potentially change as new information becomes available. Others have used the available toxicological data to develop alternative toxicity values, including a probabilistic RfDo of 1E-02 mg/kg-day developed by Thompson, et al. (2019) and a draft RfDo of 8E-05 mg/kg-day developed by USEPA. Notably, RME hazard indices for the maximally-exposed populations for each EU that are predicated on use of the NC DHHS, USEPA and Thompson RfDo values are equal to or less than 1, indicating no exceedance of available health benchmarks or of USEPA's threshold for identifying a potential human health hazard, even in the absence of drinking water treatment. In addition to the uncertainty associated with the HFPO-DA RfDo, the lack of toxicity information for other Table 3+ PFAS also introduces uncertainty to the HH-SLEA but data are not available to evaluate the potential effect, if any, on the conclusions hazard characterization.

- Laboratory Analytical Limits. For groundwater and surface water, the reporting limits (RLs) for Table 3+ PFAS were below the State's provisional health goal for HFPO-DA in drinking water of 140 ng/L, indicating the method is sufficiently sensitive for identifying concentrations that may potential pose a human health hazard. The HH-SLEA also demonstrated that methods for analyzing HFPO-DA in soil and fish tissue are sufficiently sensitive to estimate exposures that could pose a potential human health hazard based on comparisons to the NC DHHS HFPO-DA RfDo.
- Media-Specific EPCs. The SLEA was prepared to provide a screening-level evaluation of intake on a regional basis. As such, the EPCs evaluated herein are not representative of a specific exposure point. Use of EPCs based on upper-bound estimates of concentration (i.e., 95% UCLs and maximum detected concentrations) reduces the likelihood that potential intake and hazard were underestimated.
- Well Water EPCs. The primary source of uncertainty associated with well water EPCs used in the HH-SLEA was the use of untreated well water data, which does not reflect current conditions; however, even this conservative evaluation of potential intake resulted in HQs less than 1. HQs calculated for current conditions are substantially lower.
- Soil EPCs. Reliance upon a single composite soil sample in each EU is a source of uncertainty but, given that incidental soil ingestion accounts for less than 1% of the total intake of Table 3+ PFAS, it is unlikely that this uncertainty affects the overall conclusions of the HHSLEA.

The HH-SLEA demonstrates no unacceptable hazards to human receptors are anticipated from current exposures to HFPO-DA in offsite environmental media. While there are uncertainties associated with the analyses supporting the HH-SLEA conclusions, where uncertainty is evident, conservative assumptions were used (e.g., use of untreated well water, upper-bound estimates of exposure, and toxicity estimates that are two orders of magnitude higher than those developed by others). Hence, the uncertainty assessment supports that the HH-SLEA can be used to inform risk management decisions.

4.3 Ecological SLEA

Chemours performed an Ecological Screening Level Exposure Assessment (Ecological SLEA) to quantify exposure of terrestrial and aquatic ecological receptors to Table 3+

PFAS and evaluate potential hazards related to HFPO-DA. The Ecological SLEA is attached to this document as Appendix G. The Ecological SLEA evaluation indicated there were no unacceptable adverse effects expected from HFPO-DA exposures. The full details of the Ecological SLEA are described in the *Ecological Screening Level Exposure Assessment (SLEA) of Table 3+ PFAS* report provided in Attachment F.

4.3.1 Receptors and Exposure Pathways

The ecological Conceptual Site Model (CSM) reflects the potential exposure of receptors to Table 3+ PFAS, including aquatic life in the Cape Fear River and tributaries, aquatic dependent wildlife foraging in the Cape Fear River and banks, terrestrial plant and invertebrate communities, and herbivorous and invertivore wildlife and carnivorous wildlife. Exposures may potentially occur to Table 3+ PFAS via surface soil, surface water and sediment, along with potential exposures via diet items for Table 3+ PFAS that may accumulate in plants, invertebrates and fish. Representative wildlife receptors were selected to represent various feeding guilds for terrestrial birds and mammals (herbivore, invertivore) and aquatic-dependent birds and mammals (herbivore, invertivore, piscivore).

4.3.2 Exposure Quantification

Field investigations included collection of onsite and offsite soils, invertebrates and offsite vegetation, and sediment, vegetation, fish and clams from the Cape Fear River for analysis of Table 3+ PFAS. These data were used to quantify exposures to selected mammalian and avian receptors and evaluate the potential for adverse effects to wildlife from current exposures to HFPO-DA. Site-specific doses for all Table 3+ PFAS were calculated for all terrestrial and aquatic-dependent wildlife receptors (birds and mammals). Ingested doses are presented in daily dose rates per unit of body weight (mg/kg-day) and referred to as total daily intake (TDI). Terrestrial wildlife was assumed to be exposed to Table 3+ PFAS via incidental ingestion of soil during foraging, consumption of surface water and consumption of food/prey items that have accumulated Table 3+ PFAS. Aquatic wildlife receptors were assumed to be exposed to Table 3+ PFAS via incidental ingestion of sediment, consumption of surface water and consumption of food/prey items that have accumulated Table 3+ PFAS. The estimated TDI for each receptor was calculated using generic dose formulas from the Wildlife Exposure Factors Handbook (USEPA, 1993), as well as receptor-specific exposure factors as discussed in the Ecological SLEA Section 3.

4.3.3 Ecological SLEA Results

The empirical data collected under the Ecological SLEA and HH-SLEA indicated 17 of 20 Table 3+ PFAS were present in detectable concentrations in onsite soils, invertebrates, terrestrial and aquatic vegetation and/or fish, with only two Table 3+ PFAS detected in sediment, benthic invertebrates and offsite soils. Samples collected from on-site locations had higher PFAS concentrations relative to samples collected from the Cape Fear River and offsite terrestrial areas. TDIs indicated predominant exposures are related to consumption of terrestrial and aquatic plants by herbivorous vertebrate wildlife like rabbits and muskrats. Terrestrial herbivores are primarily exposed to perfluoroethoxysulfonic acid (NVHOS) and PFMOAA. Aquatic herbivores in the Cape Fear River are primarily exposed to PFMOAA followed by Byproduct 4, Byproduct 5 and PMPA. Exposures for invertivores were lower than for herbivores, with exposures primarily associated with PMPA, Byproduct 4, Byproduct 5, and R-EVE offsite, and PFMOAA and Byproduct 4 onsite. Aquatic invertivores are not highly exposed based on the currently available dataset, and though exposure to aquatic piscivores does occur with exposed primarily associated with perfluoro(3,5,7,9-tetraoxadecanoic) acid (PFO4DA), PFMOAA and Byproduct 4.

No adverse hazards were identified to ecological receptors from current exposures to HFPO-DA. The Table 3+ PFAS with the highest exposures in the most-exposed ecological feeding guilds (herbivores) in both terrestrial and aquatic habitats were NVHOS, PFMOAA, PMPA, Byproduct4, and PFO2HxA. Fish-consuming receptors were most exposed to PFO4DA. As the primary exposures are related to the onsite seep areas and consumption of plants in the offsite area, source control of air emissions and discharges to the Cape Fear River will decrease exposures to ecological receptors.

4.3.4 Ecological SLEA Uncertainties

There are a number of uncertainties related to all SLEAs, based on the use of assumed parameters for ecological modeling, spatial variation of chemicals in media, and organism habitat use patterns, therefore the assumptions used in the Ecological SLEA aimed to provide additional conservatism, i.e., protectiveness where there was significant uncertainty. Specific key uncertainties in the Ecological SLEA include:

- Lack of Toxicity Information. This analysis was unable to assess hazards to exposed receptors for Table 3+ PFAS other than HFPO-DA due to the lack of Table 3+ PFAS specific TRVs (a testing program is presently in progress to evaluate toxicity of five additional Table 3+ PFAS [Chemours, 2019]);
- Use of practical quantitation limits (PQL) for Exposure Point Concentration. If a Table 3+ PFAS was detected in some media of an EU, it was carried forward in the quantification of exposures using the PQL as the EPC for media where that compound was not detected. The use of the PQLs as EPCs leads to overestimates of exposures.
- Large Carnivores. Larger ranging carnivores that consume small birds and mammals were not included in this evaluation as the collection of small bird and

mammal tissue samples to understand exposure to these receptors is a significant undertaking and was not feasible in the SLEA development timeframe.

- Sediment and Benthic Invertebrates. The sediment and benthic invertebrates (Asian clam) samples collected from the Cape Fear River were widely non-detect for Table 3+ PFAS. However, given the noted analytical sensitivities between soil and aqueous matrices and the lower organic carbon partitioning of Table 3+ PFAS, and that Asian clams are filter feeders with a lower level of sediment association than many other benthic invertebrates, there is uncertainty that this exposure route is under represented.

This Ecological SLEA demonstrates no adverse hazards to ecological receptors are anticipated from current exposures to HFPO-DA. This was done by including a number of conservative assumptions to address uncertainties when estimating exposure of ecological receptors to Table 3+ PFAS and estimating hazards from exposures to HFPO-DA.

5 NUMERICAL MODEL

5.1 Study Objectives

The objective of the numerical modeling of onsite groundwater was to develop a platform for use in the development and evaluation of remedial alternatives, including estimation of cost. In addition, the model in the future will aid in assessing the effectiveness of remedial implementation. The model is intended to be hydraulic only, to aid in assessment of pumping and recharge reduction approaches. Model details are provided in Appendix H.

5.2 Selection of Model

The model is required to simulate saturated and unsaturated flow behaviors at the Site. The steep topography surrounding the site is challenging to simulate, and therefore a finite element model was deemed to be more appropriate than a finite difference model. Various commercially available finite element models were assessed based on their ability to meet the study objectives, their maturity and acceptance in the scientific and regulatory communities, and the familiarity of the team with the code. Finite Element subsurface FLOW system (FEFLOW) (DHI-WASY) was the most suitable numerical model based on those criteria.

5.3 Model Construction

A three-dimensional (3D) hydrostratigraphic model of the Site was constructed using CTech Earth Volumetric Studio (EVS) software (https://www.ctech.com/products /earth-volumetric-studio/). The EVS model was developed to interpolate the hydrostratigraphic model, along the horizontal and vertical directions, and develop the model mesh for the numerical groundwater model.

The EVS geologic model was translated into a series of shape files representing each of the 7 hydrostratigraphic units. The shape files were assembled and meshed within FEFLOW using the triangle mesh generation algorithm. The mesh was further refined vertically to allow for more accurate simulation of vertical gradients and hydraulic processes in the vicinity of the bluffs leading to the Cape Fear River and Willis Creek. Overall the mesh contained 1,878,129 elements and 372,054 nodes. Details are presented in the incorporated modeling report.

5.3.1 Calibration

Calibration was performed using a sequenced trial and adjustment approach. Calibration variables consisted of rainfall recharge applied to the top boundary of the model, hydraulic conductivities of the Black Creek Aquifer, the Surficial Aquifer, the Perched

Clay, and the Perched Aquifer, as well as the formulation of the constant head condition on the western boundary.

Final model calibration resulted in a Normalized Root Mean Square (NRMS) error of 12.5%. This is considered satisfactory based on the scale of the model and its intended end use in costing and preliminary design focusing on hydraulics only (as opposed to contaminant fate and transport). The majority of the error in the calibrated model occurs in the Perched Zone and will have limited effect on the ability of the model to predict capture of groundwater discharge to the surface water bodies.

5.4 Predictive Simulations

The six most representative remedy simulations are presented below in Table 8. In total, 21 simulations were conducted using the calibrated model to aid in the evaluation of an appropriate groundwater remedy.

Table 8: Predictive Model Simulations

Simulation	Description	Total Extraction Rate (gpm)	Total Diverted Flow Rate (gpm)[1]	Number of Extraction Wells
1	Extraction wells at a 50-ft spacing (30 gpm) with no barrier wall	4,920	N/A	164
2	Extraction wells at a 200-ft spacing (20 gpm) with a barrier wall between the river and the extraction wells	820	569	41
3	Extraction wells at a 50-ft spacing (variable pumping between 20 to 40 gpm) with no barrier wall	4,430	N/A	164
4	Extraction wells at a 200-ft spacing (variable pumping between 20 to 30 gpm) with a barrier wall between the river and the extraction wells	930	491	41
5	Extraction wells at a 250-ft spacing (30 gpm) with a barrier wall between the river and the extraction wells	930	489	31
6	Extraction wells at a 250-ft spacing (variable pumping between 20 to 30 gpm) with a barrier wall between the river and the extraction wells	840	611	31

Notes:

N/A – not applicable.

[1] – Diverted flow accounts for the reduced discharge to the Cape Fear River due to the barrier wall.

The various simulations can be summarized as follows:

- Simulation 1 resulted in a large groundwater depression along the Cape Fear River in areas surrounding the pumping wells. A large portion of the extracted water was from the Cape Fear River.
- Simulation 2 resulted in minimal contributing flow from the Cape Fear River. Pumping wells create a groundwater depression in portions of the extraction wells.
- Simulation 3 reduced the groundwater depressions observed at higher pumping rates (simulation 1). Pumping wells still extract water from the Cape Fear River.
- Simulation 4 increased the groundwater capture along the extents of the barrier wall in comparison to simulation 2. The variable pumping rates minimized the groundwater depressions observed along portion of the extraction wells.
- Simulation 5 decreased the groundwater depressions observed along section of the barrier wall. However, in comparison to simulation 2 mounding was observed along section of the barrier wall. Also, a portion of the flow was not captured at the edges of the barrier wall.
- Simulation 6 increased pumping at the targeted extraction wells and increased the capture of flow at the extents of the barrier wall. However, in comparison to simulation 4 mounding was observed along section of the barrier wall.

The remedy modeling results indicate that without a barrier wall, the increase in total flow due to influx of Cape Fear River water makes these types of scenarios less feasible. The scenario that best meets the hydraulic containment objectives presented in Table 8 consists of an extraction well spacing of 200 feet, with pumping rates varying between 25 and 30 gpm per well. Ideally, there would be minimal drawdown to reduce the volume of water that requires treatment while also maintaining hydraulic containment. Additional aquifer tests would be required to assess the spacing and corresponding pumping rates.

The calibrated FEFLOW model meets the requirements of the NCDEQ 2007 Groundwater Modeling Policy (NCDEQ, 2007) and supports remedy evaluation, selection and design at the Site. The calibrated model is deemed sufficiently accurate for the modeling goals of this work however new data should be incorporated into both the conceptual and numerical models when it becomes available.

Numerical modeling is an effective technique for identifying areas of uncertainty in conceptual models and source-pathway-receptor models. Based on the results of the numerical modeling program, groundwater remedy development would be supported by reducing uncertainty regarding:

- Interactions between the Surficial Aquifer and the Black Creek Aquifer along the bluffs. Additionally; and
- Distribution of groundwater flows into surface water drainage features including onsite groundwater seeps, Willis Creek and Old Outfall 002.

A combination of additional simulations and targeted field investigations (aquifer testing) to address these uncertainties is recommended before selecting a final remedy for design.

6 PROPOSED CORRECTIVE ACTIONS

This section describes the proposed corrective actions to treat groundwater and surface water where these pathways are contributing PFAS loading to the Cape Fear River, including those actions proposed in the previous Paragraph 12 submittals: the August 2019 Reduction Plan and the November 2019 Reduction Plan – Supplemental Information Report. Together these corrective actions have been developed to meet the objectives and cleanup goals that are described in Section 6.1 and Section 6.2, respectively. The detailed development of potential remedial alternatives and evaluation of technical and economic feasibility that was provided in the Paragraph 12 submittals is not reproduced in this CAP, which rather focuses on further developing the groundwater and surface water remedies that were proposed for advancement. Table 9 provides a summary, by pathway, of the results of this screening process.

The remaining subsections below provide detailed discussion for these advanced groundwater and surface water alternatives in terms of design, construction, and operation; estimation of construction and operational costs; permits anticipated to be required; and sequencing and schedule. Performance monitoring of the remedies, compliance with CO Paragraph 16, and onsite and offsite groundwater quality monitoring are discussed in Section 7.

6.1 Corrective Action Objectives

The selection of corrective actions presented in this CAP is based on the CO's remedial requirements and management goals for the Site which are as follows:

- Reducing the total loading of PFAS originating from the Site to the Cape Fear River by at least 75 percent (%) from baseline (CO paragraph 16);
- Provide whole building filtration units and/or reverse osmosis units to qualifying surrounding residents (CO paragraphs 19 and 20);
- Comply with 2L Rules (CO paragraph 16), including following the policy for the intention of the 2L Rules "to maintain and preserve the quality of the groundwaters, prevent and abate pollution and contamination of the water of the state, protect public health, and permit management of the groundwaters for their best usage by the citizens of North Carolina" (15A NCAC 02L .0103); and
- Comply with other requirements of the CO.

Table 9: Summary of Remedial Alternatives Evaluation Process

Pathway	Retained for Further Development	Not Advanced in P12 Submittals
Direct Aerial Deposition	Air Emission Control Technologies	N/A
Old Outfall 002	Capture and Treat Old Outfall 002	N/A
Groundwater Seeps	*Interim and Long-Term*: Flow Through Cells and French Drains	PlumeStop^{TM} at CFR and Willis Creek Seeps
Onsite Black Creek Aquifer Groundwater	*Interim*: Pumping from Existing Wells *Long-Term*: Onsite Barrier Wall with Hydraulic Containment	*Interim*: Pumping from Additional Extraction Wells *Long-Term*: Hydraulic Containment
Outfall 002	Sediment Removal Stormwater Pollution Prevention Plan Targeted Stormwater Control Terracotta Pipe Decommissioning Mitigation of Groundwater Intrusion	Treat all stormwater at Outfall 002 Treat all flows at Outfall 002
Willis Creek and Georgia Branch Creek	Air Emission Control Technologies Onsite Barrier Wall with Hydraulic Containment	Treat all Flows at Mouths PlumeStop^{TM} along Creek Lengths
Offsite Groundwater	Air Emission Control Technologies	Offsite Barrier Wall with Hydraulic Containment

The Table 3+ PFAS compounds at the Site have only been recently considered for environmental remediation and the availability of treatment technologies is limited at this time. This is a rapidly evolving field and new technologies may become available. Chemours' implementation of actions for these goals may be refined as both remedial technologies for PFAS develop and a greater body of scientific understanding develops regarding PFAS originating from the Site.

6.2 Cleanup Goals and Standards by Media

Pursuant to the 2L Rules and CO requirements, this section describes the development of cleanup goals for surface water and groundwater on and offsite. This section begins by describing the factors influencing the developed clean up goals, then the cleanup goals by media are described, and lastly the potential need for alternative groundwater cleanup standards in the intermediate to long term future are discussed.

6.2.1 Cleanup Goal Factors

The cleanup goals were developed based on the following five factors:

- Time horizons (Near, Intermediate, Long-Term);
- Human health exposure considerations;
- Ecological exposure considerations;
- CO requirements; and
- 2L Rules.

First, cleanup goals were developed for near, intermediate and long-term time horizons. Near term goals reflect what can be accomplished in the next two years and have an emphasis on taking actions that lead to the greatest reduction in exposures to potential receptors. Intermediate goals reflect implementing long term remedial actions and reflect presently available technologies and approaches. Long term goals reflect the long-term operation and maintenance of remedial actions and recognize that advancements in the understanding of potential toxicity of compounds and abilities to remediate compounds may evolve and lead to refinement of cleanup goals.

Second, human health exposure considerations were considered. The HH-SLEA described in Section 4.2 demonstrated that at present human HFPO-DA exposures are estimated to be below the NC DHHS chronic, long-term exposure reference dose. Furthermore, the HH-SLEA demonstrated that supplying whole building filtration systems or reverse osmosis units for qualifying residents offsite is reducing HFPO-DA (and Table 3+ PFAS) intake by over 92% further ensuring human receptor exposures remain below hazard limits for HFPO-DA, based on the NC DHHS draft oral reference dose. Therefore, the current HH-SLEA findings do not necessitate the formation of a cleanup goal.

Third, ecological exposures were considered. The Ecological SLEA described in Section 4.3 demonstrated that present ecological exposures at and surrounding the Site to HFPO-DA are not expected to result in adverse effects to terrestrial and aquatic ecological receptors. Therefore, the current Ecological SLEA findings do not necessitate the formation of cleanup goals.

Fourth, CO paragraph 16 requires, at minimum, a 75% reduction in the loading of Table 3+ PFAS originating from facility to surface water (Old Outfall 002, Willis Creek, Georgia Branch Creek, and the Cape Fear River). The Cape Fear River receives discharge from Old Outfall 002, Willis Creek and Georgia Branch Creek, onsite seeps and onsite groundwater. Therefore, reducing Cape Fear River PFAS mass loading by at least 75 % was established as a cleanup goal. Corrective actions outlined in Paragraph 12 submittals and described in this CAP are estimated to lead to greater than 75% reduction in the mass loading of Total Table 3+ PFAS to the Cape Fear River.

Last, for Corrective Actions under the 2L Rules, 15A NCAC 02L .0106 (a), "Where groundwater quality has been degraded, the goal of any required corrective action shall be restoration to the level of the standards, or as closely thereto as is economically and technologically feasible as determined by the Department in accordance with this Rule." At present, no standards exist for Table 3+ PFAS under North Carolina law, and the 2L Rules, 15A NCAC 02L .0202(c) states such "substances…shall not be permitted in concentrations at or above the PQL in Class GA or Class GSA groundwaters." At present, reducing Table 3+ PFAS concentrations in onsite and offsite groundwater to below the PQL is not technologically or economically feasible as described later in section 6.2.4. In the future, groundwater cleanup standards based on scientific studies may be developed and improvements and breakthroughs in in situ treatment of PFAS and Table 3+ PFAS may occur. For example, in late December 2019 the EPA issued a preliminary remediation goal of 70 ppt for groundwater impacted with two PFAS compounds (PFOA and PFOS)[2], showing that the state of the science is advancing as a whole for PFAS and in future science based regulatory standards may become available for Table 3+ PFAS.

Together, both regulatory standards and PFAS treatment improvements may make remediation to 2L standards possible. Until that time, alternate cleanup standards may need to be considered as described in 15A NCAC 02L .0106 (a) and (i) together and 15A NCAC 02L .0106 (k). These potential alternate cleanup criteria are described in greater detail later in sub-section 6.2.3 as well as the possibility of performing risk-based remediation as described by N.C.G.S. § 130A-310.66 et seq.

[2] EPA, 2019. The preliminary remediation goal (PRG) was set as 70 ppt (the current lifetime drinking water health advisory level) for contaminated groundwater that is a current or potential source of drinking water, where no state or tribal MCL or other applicable or relevant and appropriate requirements (ARARs) are available or sufficiently protective. The guidance recommends using a screening level of 40 ppt to determine if PFOS and/or PFOA is present at a site and may warrant further investigation.

6.2.2 Cleanup Goals by Media / Surface Water Body

Cleanup Criteria are described in Table 10 of this subsection by describing the basis of the cleanup goals for media / pathway and then describing what the developed cleanup goals are on a Near Term (2 years), Intermediate Term (up to 5years) and Long Term (> 5 years) basis.

Table 10: Cleanup Goals

Media / Pathway	Cleanup Goal Basis	Near Term (2 years)	Intermediate Term (up to 5 years)	Long-Term (>5 years)
Cape Fear River	- CO paragraph 16: minimum 75% reduction of Table 3+ PFAS Loading - Reduce HFPO-DA and Table 3+ PFAS loading concentrations such that exposures continue to decrease as provided in SLEAs.	- Begin implementation of interim actions proposed in this CAP to decrease Table 3+ PFAS loading to the Cape Fear River.	- Complete implementation of interim actions and proposed corrective actions outlined here to reduce Table 3+ PFAS loading to the Cape Fear River by at least 75% from baseline.	- Achieve 75% Table 3+ PFAS Loading Reduction; - Maintain HFPO-DA and other Table 3+ PFAS in accordance with surface water standards in the Cape Fear River.
Old Outfall 002	- CO paragraph 12: capture dry weather flows of Outfall 002 and treat to 99% removal of HFPO-DA and PFMOAA before subsequent discharge. - Supports CO paragraph 16 requirement of minimum 75% Table 3+ PFAS loading reduction in Cape Fear River. - Comply with NPDES permit.	- Implement dry weather flows capture and treat system.	- Maintain dry weather flows capture and treat system as long as needed.	- Maintain dry weather flows capture and treat system as long as needed
Onsite Groundwater Seeps	- As per Paragraph 12 Cape Fear River PFAS Loading Reduction Plan reduce Total Table 3+ PFAS mass loading to Cape Fear River. - Supports CO paragraph 16 requirement of minimum 75% loading reduction in Cape Fear River.	- Begin implementing and optimizing interim actions and long-term remedies.	- Seep treatment remedy operating to reduce Table 3+ PFAS loading as long as needed	- Maintain seep treatment remedy as needed
Willis Creek	- Achieve economically and technically feasible reductions to support CO paragraph 16 requirement of minimum 75% Table 3+ PFAS mass loading reduction in Cape Fear River. - Reduce discharge to Willis Creek of onsite Table 3+ PFAS with a process water signature	- Implement thermal oxidizer and other air abatement controls to reduce offsite groundwater concentrations over time; offsite groundwater discharges to Willis Creek. - Design and begin construction process for onsite groundwater remedy which will reduce PFAS mass loading via the Black Creek Aquifer to Willis Creek.	- Maintain air abatement controls. - On Site Groundwater Remedy will address PFAS loading to Willis Creek.	- Maintain air abatement controls. - Maintain groundwater remedy as needed

Media / Pathway	Cleanup Goal Basis	Near Term (2 years)	Intermediate Term (up to 5 years)	Long-Term (>5 years)
Georgia Branch Creek	- Achieve economically and technically feasible reductions to support CO paragraph 16 requirement of minimum 75% Table 3+ PFAS mass loading reduction in Cape Fear River	- Implement thermal oxidizer and other air abatement controls to reduce offsite groundwater concentrations over time;	- Maintain air abatement controls.	- Maintain air abatement controls.
Onsite Groundwater	- Reduce discharge of PFAS with a PFAS process water signature to Cape Fear River and to Willis Creek to support CO paragraph 16 requirement of minimum 75% Table 3+ PFAS mass loading reduction in Cape Fear River (Process water signature discharge to Old Outfall 002 is addressed by Old Outfall 002 capture and treatment system; PFAS historically released in process water does not discharge to Georgia Branch Creek) - Comply with 2L Rules	- Implement interim actions. - Conduct pre-design investigations for on-site groundwater remedy and treatment.	- Implement groundwater remedy.	- Evaluate 2L cleanup standards based on potentially existing cleanup standards developed from newly available scientific studies and potentially more effective remedial approaches recently developed. Presently both technically and economically infeasible to cleanup onsite groundwater to PQLs.
Offsite Groundwater	- Provide replacement drinking water to surrounding residents where groundwater based on requirements of CO paragraphs 19 and 20 - Maintain human exposures to HFPO-DA below the North Carolina Department of Health and Human Services (NCDHHS) reference dose (achieved per HH-SLEA results and replacement drinking water actions)	- Provide replacement drinking water. - Implement thermal oxidizer and other air abatement controls to reduce offsite groundwater concentrations over time.	- Maintain provision of replacement drinking water as long as needed - Maintain air abatement controls.	- Maintain provision of replacement drinking water as long as needed - Maintain air abatement controls.

Media / Pathway	Cleanup Goal Basis	Near Term (2 years)	Intermediate Term (up to 5 years)	Long-Term (>5 years)
Onsite and Offsite Soils	- Maintain human exposures to HFPO-DA below the NCDHHS reference dose (achieved per HH-SLEA results and replacement drinking water actions) - Maintain ecological exposures below adverse effects levels (achieved per Ecological SLEA results) - 2L requires removal or control of secondary sources to groundwater such as contaminated soils. Per information presented in Section 3.6 much more mass is in groundwater than in soils suggesting soil remediation would have a reduced benefit.	- Implement thermal oxidizer and other air abatement controls to reduce PFAS deposition rates to on and offsite soils.	- Maintain thermal oxidizer and other air abatement controls to reduce PFAS deposition rates to on and offsite soils.	- Maintain thermal oxidizer and other air abatement controls to reduce PFAS deposition rates to on and offsite soils.
Outfall 002	- The NPDES permit will develop effluent limits for Outfall 002 - Outfall 002 actions proposed in Chemours CO paragraph 12 Cape Fear River PFAS Loading Reduction Plan	- Comply with NPDES permit - Begin implementing actions proposed in the Reduction Plan	- Comply with NPDES permit (permit is for 5 years) - Implement actions proposed in the Reduction Plan	- Re-apply for NPDES permit - Maintain actions proposed in the Reduction Plan

6.2.3 Potential Future Alternate Groundwater Cleanup Standards

In the future NCDEQ and Chemours may need to consider alternate cleanup standards conceived under 15A NCAC 02L .0106 (a) and (i) together and 15A NCAC 02L .0106 (k) individually or risk-based remediation as described by N.C.G.S. § 130A-310.66 et seq.

6.2.4 Potential Future Alternate Groundwater Cleanup Standard 15A NCAC 02L .0106 (a) and (i)

15A NCAC 02L .0106 (a) and (i) allows for consideration of alternate cleanup criteria when it states in (a) that the goal of corrective action is, "restoration to the level of the standards, or as closely thereto as is economically and technologically feasible". And (i) states that "the Secretary shall consider the extent of any violations, the extent of any threat to human health or safety, the extent of damage or potential adverse impact to the environment, technology available to accomplish restoration, the potential for degradation of the contaminants in the environment, the time and costs estimated to achieve groundwater quality restoration, and the public and economic benefits to be derived from groundwater quality restoration." All these factors are relevant to the Chemours Fayetteville Works Site and are examined below.

<u>Technical and Economic Infeasibility</u>

The technical and economic infeasibility of Table 3+ PFAS remediation is driven by two factors, (a) the large areal extent PFAS are detected and (b) the lack of remedial technologies that are effective over large areas and effectively destroy PFAS mass in-situ at a technically achievable and affordable scale. To date Table 3+ PFAS have been detected over an area of 70+ square miles (over 45,000 acres). The size of the area encompasses hundreds of private land parcels and any remedial construction activities using currently available remedial technologies (excavation and groundwater extraction) would be very disruptive to the local community and this disruption would continue for a lengthy period of time. Any remedy which in principle could help make progress towards PQLs over this large area would cost in the billions to tens of billions of dollars. However, at this time these hypothetical remedies are not considered necessary to protect human health or ecological receptors as presented in the HH-SLEA and Ecological SLEA reports.

Additionally, there are no currently available remedies that are expected to be able to meet PQLs over an area this large. There are two candidate remedial approaches (a) in situ sorption (i.e. PlumeStop™) or pumping and treating. PlumeStop™ leaves the PFAS in place in the aquifer and over time; with additional loading these PFAS would desorb from the emplaced PlumeStop™ and become mobile again. For PlumeStop™ to meet PQLs additional product would have to be applied to the entire aquifer system across the impacted 70+ square miles repeatedly until another technology is invented that destroys the PFAS mass in place – a logistically impossible (e.g. access agreements) and economically prohibitive task (lack of PlumeStop™ supply, cost in the tens of billions of dollars).

Meanwhile, though pump and treat systems do remove mass from the aquifers, they reach points of diminishing returns where aquifer concentrations stay constant and where the technology is applied to extremely large areas. Pump and treat systems are now conceived by the remediation industry as systems to control contaminant migration, not systems to remove contaminant mass and clean aquifers of contaminants. A pump and treat system applied at the Site with the goal of restoring groundwater to PQLs would cost an economically infeasible amount of over a billion dollars and would almost certainly not achieve PQLs and not achieve any additional benefit in loading reductions to the Cape Fear River greater than those already proposed in this CAP. Likewise an offsite pump and treat system would be technically challenging to infeasible and cost an estimated tens to hundred billion dollars and achieve limited to no benefit in reducing exposures and hazards than actions already proposed and in progress.

Extent of any violations

Chemours has entered into the CO to comprehensively address DEQs concerns. Chemours has and is working expeditiously with DEQ to address releases and emissions to the environment.

Extent of any threat to human health or safety

The HH-SLEA demonstrated that offsite human exposures, both in the surrounding area, and for downstream river water users, to historically deposited PFAS and PFAS in the Cape Fear River are below the NCDHHS reference dose. Further, for private well users, replacement drinking water will reduce HFPO-DA and Table 3+ PFAS intake by over 92% and for Cape Fear River water users' actions outlined in this CAP will lead to at minimum a 75% reduction in Table 3+ PFAS intake. These actions will provide further protectiveness to human health and safety.

Extent of damage or potential adverse impact to the environment

The Ecological SLEA (Appendix G) concluded no adverse hazards to ecological receptors are anticipated from current exposures to HFPO-DA.

Technology available to accomplish restoration

There does not exist any proven technologies for passive in situ PFAS degradation. In situ sorption can lead to desorption in the future, and ex situ treatment will become asymptotic and not achieve cleanup goals.

Potential for degradation of the contaminants in the environment

Table 3+ PFAS are not expected to degrade in a reasonable time period in the environment, and therefore this is not a mechanism that will support concentration reductions.

Time and costs estimated to achieve groundwater quality restoration

Based on professional opinion the costs for on and offsite remediation to PQLs would exceed billions to potentially tens of billions of dollars and the timeframe would be on the order of multiple decades.

Public and economic benefits to be derived from groundwater quality restoration

There are limited to no additional public or economic benefits to remedial actions outside of those already proposed in the CAP. This CAP describes replacement drinking water actions to reduce intake of the most exposed offsite residents by over 92% to Table 3+ PFAS and this CAP describes actions to reduce Cape Fear River PFAS mass loading by over 75%. Even in the most conservative, hypothetical scenarios evaluated these actions will maintain river HFPO-DA concentrations below 140 ng/L at potential downstream raw water intakes.

6.2.5 Potential Future Alternate Groundwater Cleanup Standard 15A NCAC 02L .0106 (k)

15A NCAC 02L .0106 (k) allows for alternate cleanup standards by demonstrating the following seven criteria. Each of them has or will be met here:

1. All sources of contamination and free product have been removed or controlled

As described in previous sections of this CAP, air emission sources are being controlled, including by a state-of-the-art thermal oxidizer that will reduce aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, with expected comparable reductions for other PFAS. Chemours' process water is captured and shipped offsite and is not released through the WWTP and the Site Conveyance Network to the Cape Fear River. Sewers leaking process water were decommissioned and re-routed aboveground. There is no free product discharged, and all sources of contamination have been removed or are being substantially controlled and, as shown in Section 3, PFAS at the Site are mostly found in groundwater.

2. Time and direction of contaminant travel can be predicted with reasonable certainty

Travel times and directions for PFAS contamination present onsite and offsite can be estimated using a substantial data set and the numerical modeling work (Section 5) undertaken on behalf of Chemours. Specifically, the numerical model can be used to estimate groundwater travel times which can then be combined with the retardation coefficients presented in Section 3.8 of this CAP.

3. Contaminants have not and will not migrate onto adjacent properties, or such properties are served by an existing public water supply system dependent on surface waters or hydraulically isolated groundwater

Historical process water releases to groundwater are hydraulically isolated from private wells and the process water PFAS signatures have not been detected in any private or offsite wells, as described in Section 3 of this CAP. Where PFAS are present offsite at private wells, they originate from aerially deposited PFAS. Offsite groundwater wells that contain Table 3+ PFAS have PFAS signatures consistent with aerial deposition. With respect to those wells, offsite migration air abatement measures that have been installed by Chemours. including the thermal oxidizer, are mitigating PFAS air emissions that lead to offsite deposition. Moreover, parties using offsite groundwater wells for drinking water purposes, where they qualify, are being provided with replacement drinking water supplies by Chemours per CO criteria and requirements.

4. The standards specified in Rule .0202 of this Subchapter will be met at a location no closer than one year time of travel upgradient of an existing or foreseeable receptor, based on travel time and the natural attenuation capacity of subsurface materials or on a physical barrier to groundwater migration that exists or will be installed by the person making the request

As noted above, the existing receptors that have been the focus of abatement measures are the offsite drinking water wells, which may have residual PFAS from prior air emissions. The thermal oxidizer and other air abatement measures will substantially prevent further PFAS contamination from reaching these receptors. Where offsite migration via aerial emissions has occurred, private well receptors are being provided with replacement drinking water supplies by Chemours per CO criteria and requirements. Moreover, existing onsite groundwater contamination is not expected to travel to or impact receptors other than surface waters, which in turn is the subject of the next criterion.

5. If the contaminant plume is expected to intercept surface waters, the groundwater discharge will not possess contaminant concentrations that would result in violations of standards for surface waters contained in 15A NCAC 02B .0200

There are no 2B standards for Table 3+ PFAS, so there will not be violation of any such standards in surface water caused by any contaminant plume from the Site. There is a State health advisory level for HFPO-DA in drinking water, which is not a 2B standard. The health advisory has not been exceeded in the Cape Fear River since 2017 when Chemours began measures to control PFAS emissions and releases at the Site. Moreover, this CAP proposes active remediation actions to reduce Table 3+ PFAS loading to the Cape Fear River by greater than 75%.

6. Public notice of the request has been provided in accordance with Rule .0114(b) of this Section

DEQ is required to provide public notice of this CAP under the CO, so public notice will be provided. In addition, if necessary, a public notice can be made per Rule 0.114(b).

7. The proposed CAP would be consistent with all other environmental laws

Actions proposed in this CAP are fully consistent with all other environmental laws, including those requirements set forth in the CO and permits. For example, the air abatement measures are consistent with and have been permitted under the Clean Air Act.

6.2.6 Potential Future Risk-Based Remediation

North Carolina law as described in N.C.G.S. § 130A-310.66 et seq. allows for risk-based remediation. Specifically, the stated purpose of Risk-Based Remediation is:

> *It is the purpose of this Part to authorize the Department to approve the remediation of contaminated sites based on site-specific remediation standards in circumstances where site-specific remediation standards are adequate to protect public health, safety, and welfare and the environment and are consistent with protection of current and anticipated future use of groundwater and surface water affected or potentially affected by the contamination.*

As the corrective actions proposed in this CAP are completed and additional toxicity data and relative source contribution data (e.g. what percentage of HFPO-DA intake comes from drinking water) are gathered for Table 3+ PFAS, Chemours and NCDEQ can potentially evaluate the suitability of applying site-specific remediation standards and following the process outlined by N.C.G.S. § 130A-310.66 et seq.

6.3 Proposed Remedial Alternatives

The detailed development of remedial alternatives and evaluation of technical and economic feasibility that was provided in the Paragraph 12 submittals (Reduction Plan and the Supplemental Information Report) is not reproduced in this CAP. The feasibility study assessed and scored potential remedial alternatives based on five criteria (Protection of Public Health and the Environment through Reduction of PFAS Mass Loading; Adverse Environmental Effects; Technical Feasibility and Effectiveness; Timing; and Economic Feasibility). This CAP focuses on the groundwater and surface water remedial alternatives that were considered to satisfactorily meet these five criteria.

For groundwater and surface water remedies that were advanced, the following sections provide a detailed description, estimated reduction in PFAS that may be achievable, implementation schedule, and estimated cost. Construction and annual operating costs for each alternative have been estimated with a range of -30 % to +50 %, and the 20-year net present value (NPV) is estimated at a 3.5% discount rate; cost detail sheets are provided in Appendix J. Cost estimates are not intended for budgetary or future planning purposes; they have been prepared from the currently available information to facilitate an inter-alternative comparison. The final costs of any selected alternative will depend on final approved design, actual labor and material costs, and competitive variable factors.

As has been previously noted, Table 3+ PFAS at the Site are present in three aquifer units (Perched, Surficial and Black Creek) and over an extensive land area. PFAS are relatively recent compounds being considered for environmental remediation and as such there are few treatment technologies with full-scale demonstrations of effectiveness. PFAS remediation is a rapidly evolving field and new technologies may become available and suitable for the PFAS at the Site that would expand the set of alternatives available for consideration. Therefore, the set of remedial alternatives considered for this Site are subject to enhancement over time and re-evaluation of the technical and economic feasibility.

6.3.1 Pathway: Direct Aerial Deposition

Direct aerial deposition of PFAS emissions from the facility has the potential to result in mass loading to surface water bodies; however, the mass loading model estimated that aerial deposition contributed less than 2% of the mass loading observed in the Cape Fear River. Aerial deposition was identified as a pathway of concern primarily due to offsite drinking water wells. The remedial approach identified to mitigate impacts to offsite drinking water wells is a series of air emission control technologies, providing temporary alternate drinking water sources and long-term water treatment to effected households.

Pursuant to Paragraph 7 of the CO, Chemours completed a number of operational improvements to control air emissions. In November 2018, Chemours installed a packed bed scrubber to control emissions from the Division Waste Gas Scrubber and in December 2018 Chemours completed the tie-in of the Carbon Absorber unit for the Second Phase Scrubber at the Vinyl Ethers North Plant. By December 31, 2019, Chemours is completing installation of a Thermal Oxidizer to control air emissions of PFAS from process streams from the Monomers IXM Area. As required by the CO, the thermal oxidizer will dramatically reduce aerial PFAS emissions from the Site, with reduction of aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, and expected comparable reductions for other PFAS. The reduction of PFAS emissions to air will over time result in lower concentrations of PFAS in offsite soils and groundwater and lead to reductions of loading to Willis Creek, Georgia Branch

Creek and the offsite Cape Fear River. The total construction cost for the thermal oxidizer is expected to be approximately $100 million or greater (a cost detail sheet is not provided in Appendix I as this remedy is near completion).

6.3.2 Pathway: Old Outfall 002

The Old Outfall 002 (OOF2) is a natural feature that discharges to the Cape Fear River. Perched zone and surficial aquifer groundwater also discharge to this feature. Since Site groundwater has elevated PFAS concentrations, OOF2 also has elevated PFAS levels. The results of the Mass Loading Model indicate OOF2 is one of the primary contributors of PFAS mass loading originating from the facility to the Cape Fear River, estimated to contribute about 26% of observed mass loading (average of the May, June, and September 2019 sampling data).

As described in Proposed Action 1 of the Reduction Plan, Chemours will continue to comply with the existing CO requirements by implementing an ex situ capture and treatment remedy for Old Outfall 002. This process is currently in the detailed design and permitting phase. Chemours provided details on the approach for treatment in the Old Outfall 002 Engineering Report (Parsons, 2019b) and Old Outfall 002 Engineering Alternatives Report (Parsons, 2019a). A process flow diagram of the treatment process is shown in Figure 5. Based on the most recent flow measurements, the dry weather baseflow is between 500 and 750 gpm; therefore, the facility is being designed to treat up to 750 gpm. The design of the treatment system is intended to be modular and scalable if additional capacity is needed.

The treatment system is required to be constructed and operational by September 30, 2020, assuming permits are issued in a timely manner. In order to continue and accelerate progress on implementing this remedy, Chemours is clearing the land where the Old Outfall 002 treatment system will be located and is arranging for power to be available at this location by early 2020. Chemours is currently soliciting bids from water treatment vendors to provide the treatment system.

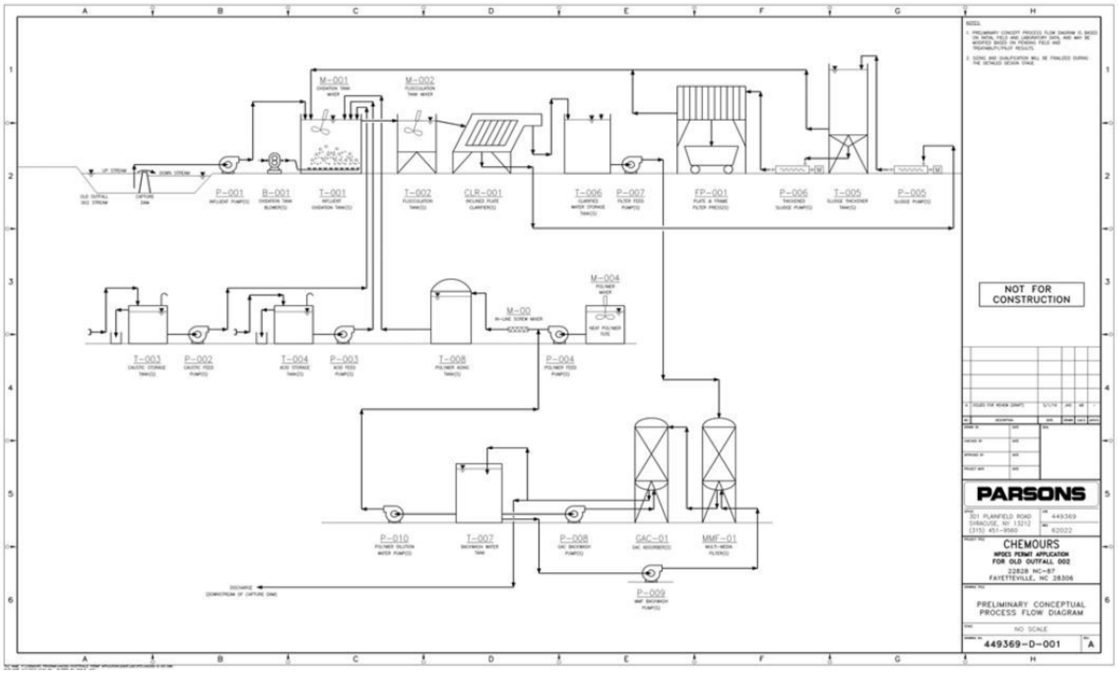

Figure 5. Old Outfall 002 Treatment System Process Flow Diagram

<u>Schedule</u>

Task	Duration (months)	2019				2020			
Geotechnical Investigation	2								
Electrical Enabling Package	3								
Electrical Upgrades (EMC)	6								
Prepare RFP for WTP	1								
Bidding and Award (WTP Only)	2								
Lift Station/Dam Design	2								
NPDES Permitting (1)	9								
Lift Station/Dam Construction	3								
WTP Design/Procurement	6								
Startup	1								

1 - Task timing is dependent upon agency approval timing

Cost

Costs for the OOF2 system have been previously presented in several submittals, including the Old Outfall 002 Engineering Alternatives Analysis (EAA) (Parsons, 2019b) and Reduction Plan Supplemental Information Report (Geosyntec, 2019h). Over time, the design of the system has progressed, and costs have been refined based on new flow measurements and data from the pilot treatment study (Parsons, 2019c). Chemours is currently evaluating the need for iron removal at the facility which would reduce the construction and operational requirements of the facility. The cost estimate was prepared without iron removal or a treatment building. Construction cost was estimated to be $7 to 15 million, annual O&M costs are estimated to be $1 to 2 million, and the 20-year NPV is $21 to 45 million.

It is noted that the total water balance for the comprehensive site remedies, as detailed in the following sections, may add additional water volume from the capture of seeps, Black Creek aquifer groundwater, and targeted stormwater. Based on engineering evaluations conducted to date, it appears to be more cost effective to consolidate all flows and convey captured water to the same location as the OOF2 system. Since the OOF2 system is likely to be sequenced first, a modular engineering approach will be employed, to which scaling up additional flow capacity over time is facilitated with skid-mount systems, a lack of fixed structures to the extent practical, and an overall adaptive management approach.

Presentation of cost estimates for seep, groundwater, and stormwater treatment in the following sections will note where applicable how incorporation of water treatment costs has been estimated relative to the baseline cost of the OOF2 system.

6.3.3 Pathway: Groundwater Seeps

Four groundwater seeps discharging from the bluff slope directly to the Cape Fear River were identified and described in the Seeps and Creeks Investigation report (Geosyntec, 2019b). The Mass Loading Model estimated that the onsite seeps discharging to the Cape Fear River contributed between 24% and 42% of PFAS mass load (on average, about 33% based on the May, June, and September 2019 sampling events).

Table 11: PFAS Loading from Seeps

Seeps	Flow Rate May 2019 (gpm)	T3+ PFAS May 2019 Concentration (ng/L)	Mass Loading (ug/s)
Seep A	120	300,000	2,270
Seep B	100	310,000	1,960
Seep C	30	350,000	660
Seep D	30	170,000	320
Total Cape Fear River Seeps	**280**	**N/A**	**5,200**

Notes:
Total Table 3+ PFAS concentrations come from the May 2019 sampling event for illustration purposes, as reported in the Seeps and Creeks Investigation (Geosyntec, 2019b). June 2019 and September 2019 sampling data not shown for clarity.
T3+ PFAS – Results of Table 3+ PFAS analytes summed
gpm – gallons per minute
ng/L – nanograms per liter
µg/s – micrograms per second

Interim Remedial Alternative for Seeps

As described in the Reduction Plan Supplemental Information Report, a combination of flow-through cells and ex situ capture using French drains is proposed as an interim remedial approach for the four onsite seeps. The approximate location of the seep remedies is shown below in Figure 6. The flow-through cell interim actions would start at Seep A with implementation progressing successively through Seeps B and C where lessons learned from the construction and operation of the flow-through cells at the prior seeps would be used to design and operate the subsequent flow-through cells.

An ex-situ capture French drain would be installed at Seep D. This method, while more power intensive and disruptive to habitats does have a higher certainty for water treatment capabilities and would serve as a pilot location of this option.

- *Seep A → Flow-Through cell – Phase 1*
- *Seep B → Flow-Through cell – Phase 2*
- *Seep C → Flow-Through cell – Phase 3*
- *Seep D → French Drain (to OOF2 treatment system)*

An adaptive management approach will be employed when implementing the above. For example, if flow-through cells in Seep A are determined to be ineffective or impractical to implement, while the French Drain in Seep D is performing as intended, then French

Drains may be installed in additional seeps. Detailed descriptions of the two types of seep remedies are provided in the following sections.

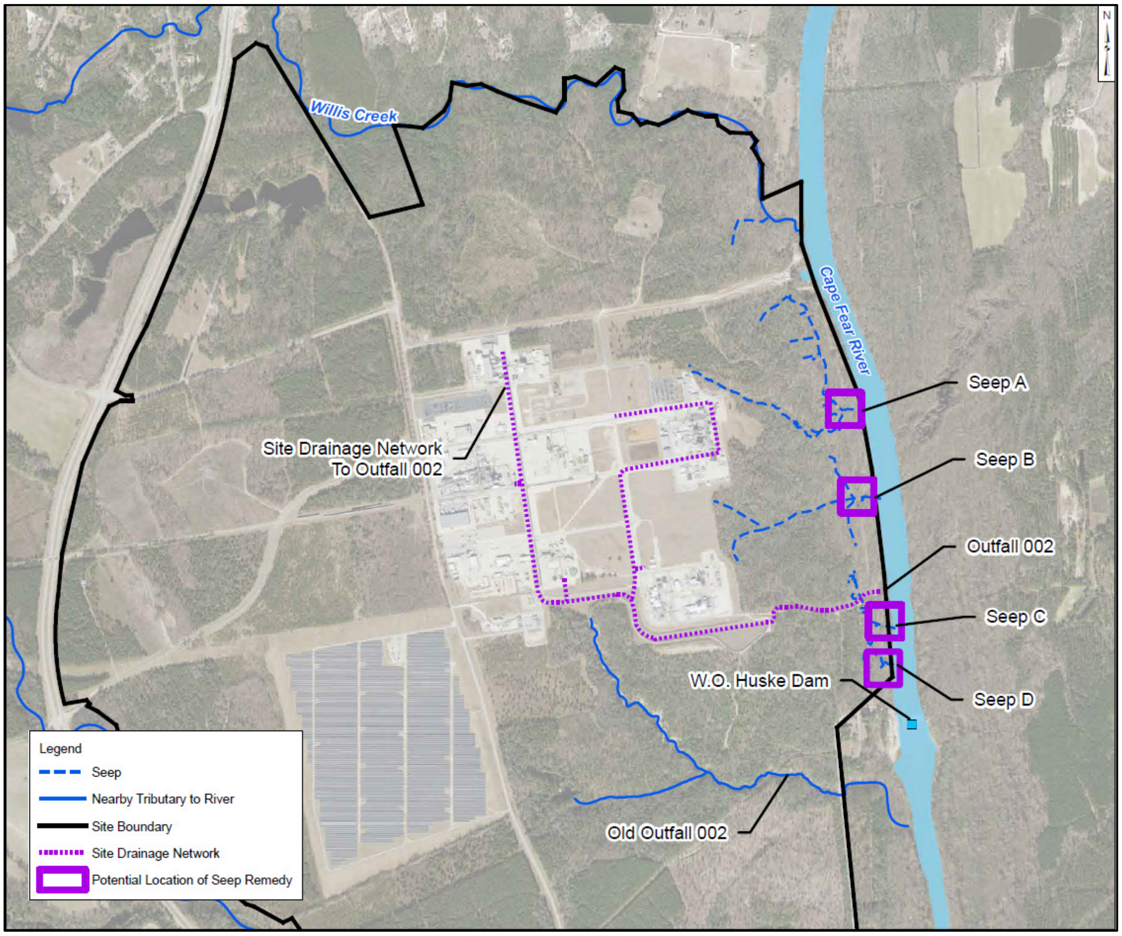

Figure 6: Location of Seep Remedial Alternatives

Flow-Through Cells

Interim application of flow-through cells would involve the installation of V-shaped sheet pile walls to guide seep water discharge through a controlled structure for on-location treatment. Large wire baskets (gabions), filled with granular activated carbon (GAC) would be installed in the discharge structures such that the water discharging from each seep location would flow through the GAC filled gabions. The PFAS compounds in the seep water would be sorbed by the GAC in the gabions and the treated water, containing much lower concentrations of PFAS compounds, would flow out the downhill side of the gabions.

Installation of the seep flow-through structures would commence after the river access road and all clearing and grubbing is complete. It is assumed that a total of 16 15-foot lengths of standard steel 22-inch wide sheet pile will be installed at each seep location. The sheet pile will be driven vertically into the ground to a depth of approximately 11 ft bgs to form a V-shaped sheet pile wall centered on and oriented perpendicular to the seep discharge channel. The center 2 sheet piles will be driven an additional approximate 3 ft to form a window in the middle of the sheet pile wall such that seep water can flow through the wall. A steel plate approximately 44-inches wide and 72-inches long will be placed flat side down in the sheet pile window and welded in place (to the sheet pile) to provide a flat stable surface for the GAC filled gabions.

Each gabion will be lined with geotextile fabric and filled with new, unused GAC. The geotextile fabric liner will then be fastened closed and the top of the gabions will be closed and fastened with steel wire such that the gabions can be moved. Three gabions will be installed first in the seep A structure as depicted in Figure 7 below using an excavator and load straps or equivalent. After installation, the gabions will be secured with sandbags to ensure they stay in place.

Construction of the flow-through cells is not anticipated to require regulatory approval via NPDES, as there is no discharge of waste, but would likely require approval from United States Army Corps of Engineers (USACE) under Section 404 of the Clean Water Act. It is assumed that the permitting pathway would be similar to that obtained for the OOF2 structures, which were permitted under Nationwide Permit (NWP) 38 (Cleanup of Hazardous and Toxic Waste) in October 2019.

It is anticipated that the first structure will be constructed at Seep A, and operated for approximately 4-months during which performance and operational data will be collected to assess system performance. Lessons learned and performance upgrades developed during this time frame at Seep A will be incorporated as design modifications for potential application at subsequent seeps.

Ex Situ Capture French Drains

This interim remedial measure involves the installation of a French drain or equivalent sump to capture seep water discharge for subsequent conveyance to the planned treatment plant to be located at OOF2. The French drain would consist of a permeable trench excavated across the seep with perforated piping to collect the water, and a sump pump to convey the captured seep water to the river access road pipeline for subsequent conveyance to the planned OOF2 treatment system for treatment and subsequent disposal.

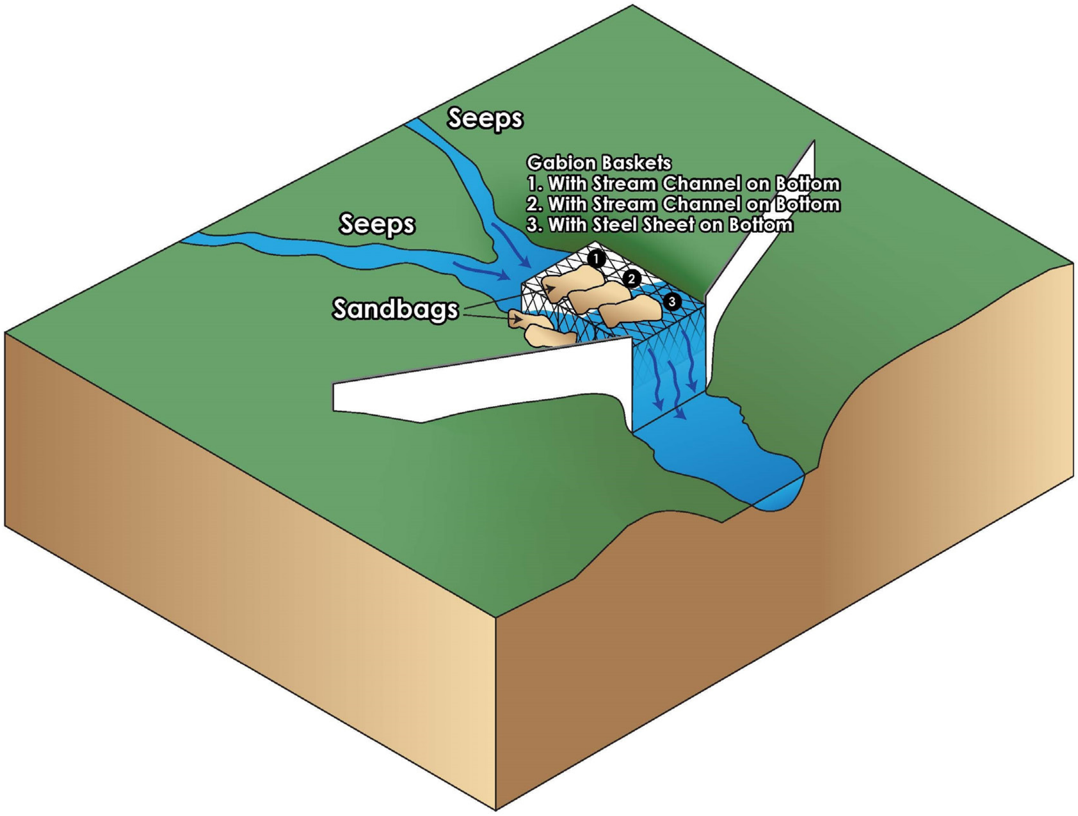

Figure 7: Conceptual Diagram of Seep Flow Through Passive Treatment

After supporting infrastructure is in place, including roads, power, and conveyance lines, a small catch basin will be excavated upstream from the planned French drain location. A portable pump with sufficient capacity for total seep flow will be placed in the basin with the pump discharge hose established to pipe water from the basin around the planned French drain location for subsequent discharge downstream from the construction area. Temporarily diverting seep discharge flow around the construction area will allow for safe and efficient French drain installation.

French drain construction is anticipated to consist of geotextile fabric lining, permeable backfill (2-inch diameter rocks), and a horizontal perforated pipe at the bottom and a vertical “sump” pipe at one end. The trench will be approximately 20-ft long and 6 ft deep with the bottom of the trench sloping to one end. After the piping is installed and the trench is backfilled, it will be armored at the ground surface with an additional layer of geotextile and concrete paver blocks to prevent erosion during storm events. A conceptual diagram is shown below in Figure 8.

After the French drain installation, a submersible pump will be installed in the vertical sump, wired to provide power, connected to the previously installed piping and function tested to ensure proper operation. The temporary seep water diversion pump and discharge hose will be removed, and the seep collection system will be put in operation.

Construction of the French drain is anticipated to require NPDES permit approval, or modification of the existing Site NPDES permit, due to the additional discharges of treated water. As with the flow-through cells, the French drains are anticipated to also require USACE NWP 38 permitting.

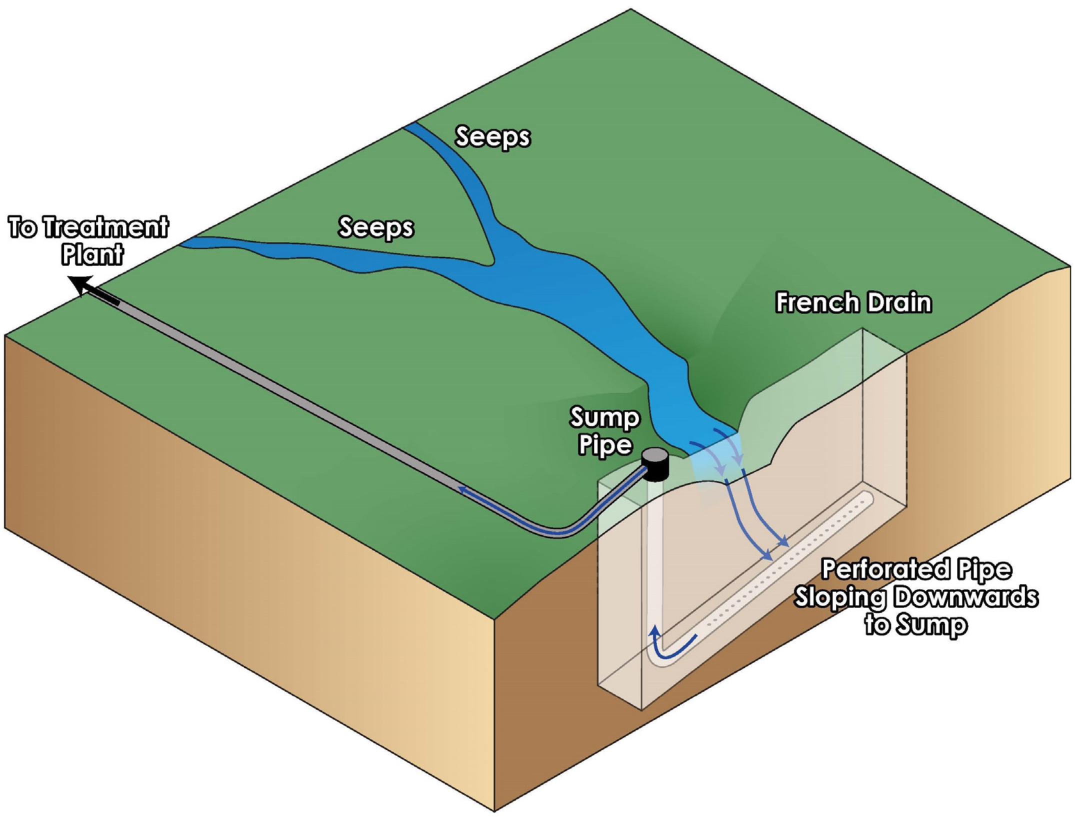

Figure 8: Conceptual Diagram of Seep French Drain Ex Situ Capture

<u>Cost</u>

The +50/-30% estimated construction cost for the interim application of flow-through cells for Seeps A through C and a French drain in Seep D is $980,000 to 2,100,000. The annual O&M cost is estimated to be between $400,000 to $870,000. Costing estimates are provided in Appendix I.

For simplicity, as interim measures are defined as implementable within two years, NPV calculations were not performed.

Long-Term Remedial Alternative for Seeps

It is anticipated to operate the interim seep actions discussed above for a period of two years during which the performance of each approach can be monitored and optimized, after which the long-term remedy will be selected. It cannot be predicted with certainty at this time which method will perform optimally at each seep.

For the purposes of this CAP, a low range cost estimate has been prepared, which assumes that the interim application of flow-through cells at Seeps A-C and a French drain at Seep D will perform as intended, and thus no additional construction costs would be required. As above, the +50/-30% estimated construction cost is $980,000 to 2,100,000, the annual O&M cost is estimated to be between $400,000 to $870,000, and the 20-year NPV is estimated to be $6.3 to 13.5 million.

In contrast, a high range cost estimate has been prepared, which assumes that the flow-through cells at Seeps A-C will not perform as intended, and that French drains will ultimately be required at all four seeps. In this scenario, the +50/-30% estimated construction cost is $8.9 to 19.1 million, the annual O&M cost is estimated to be between $400,000 to 840,000, and the 20-year NPV cost is estimated to be $15 to 32 million. Costing estimates are provided in Appendix I.

6.3.4 Pathway: Onsite Black Creek Aquifer Groundwater

The Black Creek Aquifer is interpreted to be the only transmissive groundwater zone at Site in contact with the Cape Fear River. The Mass Loading Model estimated that the Black Creek aquifer groundwater discharging to the Cape Fear River contributed between 14% and 22% of PFAS mass load (on average, about 18% based on the May, June, and September 2019 sampling events).

Interim Remedial Alternative for Black Creek Aquifer: Groundwater Extraction from Existing Monitoring Wells

As described in the Reduction Plan Supplemental Information Report, the interim remedial alternative advanced for groundwater consists of installing submersible electric pumps in seven existing black creek monitoring wells and pumping the water to the OOF2 treatment plant for treatment and discharge. Submersible electric pumps would be installed in seven site wells: BCA-01, BCA-02, PW-9D, PW-10DR, PW-11, PW-14, and PW-15R (as shown in Appendix B). Piping would be installed to convey the water to the proposed OOF2 treatment plant, potentially above-grade as a time-saving measure. Based on available information, it is anticipated that a sustained flow rate of 2 gpm from each well could be achieved. Therefore, the total flow would be 14 gpm. It is assumed that there will be sufficient excess capacity at the OOF2 treatment plant and that the discharge could be covered under the current NPDES permit application for that plant without additional modification.

Schedule

Task	Duration (months)	Year 1			
Detailed Design	2				
Contracting	1				
Installation and Operation	9				

Cost

Costs were estimated and considered to be accurate within the +50/-30 % range. The construction costs range from $560,000 to 1.2 million, annual O&M costs are $48,000 to 102,000. Costing estimates are provided in Appendix I. For simplicity, as interim measures are defined as implementable within two years, an NPV calculation was not performed.

Long-Term Remedial Alternative for Black Creek Aquifer: Barrier Wall and Groundwater Capture

At the time of the November 4 Reduction Plan Supplemental Information Report submittal, the numerical model had not been calibrated, so it was not yet clear what would be the most efficient method to mitigate the flux of onsite groundwater to the Cape Fear River. Based on the numerical modeling scenarios detailed in Section 5, it is anticipated that hydraulic containment coupled with a barrier wall will most efficiently capture the necessary component of the Black Creek aquifer without also drawing in the river.

Extensive investigation, analysis, and numerical model refinement would be required to properly design a remedy of this scale. A geotechnical investigation would be required along the alignment (anticipated boring frequency every 100 linear feet) to determine the depth and penetration resistance of the confining unit. Additional delineation consisting of borings, wells, and in-river flux analyses may also be utilized to properly target the optimal areas for containment needed to achieve the corrective action objectives. Finally, pilot testing, consisting of extraction well drilling and aquifer testing at multiple locations along the alignment, would be performed to determine the optimal well spacing and extraction rates. It is anticipated that in the course of two years, these activities would allow for model refinement and completion of design and permitting effort. In the absence of this pre-design data, the following discussion of a long-term groundwater remedy is still highly conceptual.

Figure 9 shows the area of groundwater with a process water PFAS signature that is potentially discharging to the Cape Fear River and Willis Creek. It is anticipated that hydraulic containment via extraction wells and a vertical barrier wall would be installed within this area, with the exact span and position to be determined after the pre-design investigations are complete. It is anticipated that the barrier wall would be constructed either with a one-pass trencher, as a soil-cement-bentonite slurry wall, or with steel sheet piles that are driven into the ground and interlocked. Both options are suitable means to mitigating the flow of groundwater, as slurry walls typically achieve a permeability of 10^{-7} centimeters/second.

While the slurry wall is considerably more cost-effective than steel, spoils management and sensitivity of disturbing the land surface near the river will require more detailed evaluation and potentially more site preparation to key in trenches that can manage the excess spoils that are generated during the mixing process. Nevertheless, it is anticipated that these measures can be adequately accounted for in the design process, and slurry walls will be considered the presumptive barrier method, with steel sheet piles as a contingency plan should further investigation indicate that the slurry walls cannot be managed appropriately in the field. A range of costs is provided for both options, as discussed later in this section.

Groundwater could be extracted from a series of vertical wells or horizontal wells. For the purpose of this analysis, vertical wells were assumed; however, the final design would utilize the most efficient option. The numerical model was utilized to estimate that the extraction well spacing behind a conceptual 8,500-foot long barrier wall would be 200 ft, and that extraction rates would vary from 20 to 30 gpm along the alignment, depending on localized hydrogeologic parameters (see Section 5 for more detail). This would result in approximately 930 gpm (1.3 MGD) of extracted groundwater.

It was assumed that the well pumps would feed into a common high-density polyethylene (HDPE) force main for distribution to the OOF2 treatment system location. Pipe sizing would range from 2 to 24 inches in diameter, depending on the estimated head loss, which is a factor of flow rate and distance from the system. It is assumed that the influent median PMPA and PFMOAA concentrations would be 8,200 and 150,000 ng/L, respectively. It is assumed that PFMOAA is the driving influent COC for GAC utilization, and that 99% removal would be the objective.

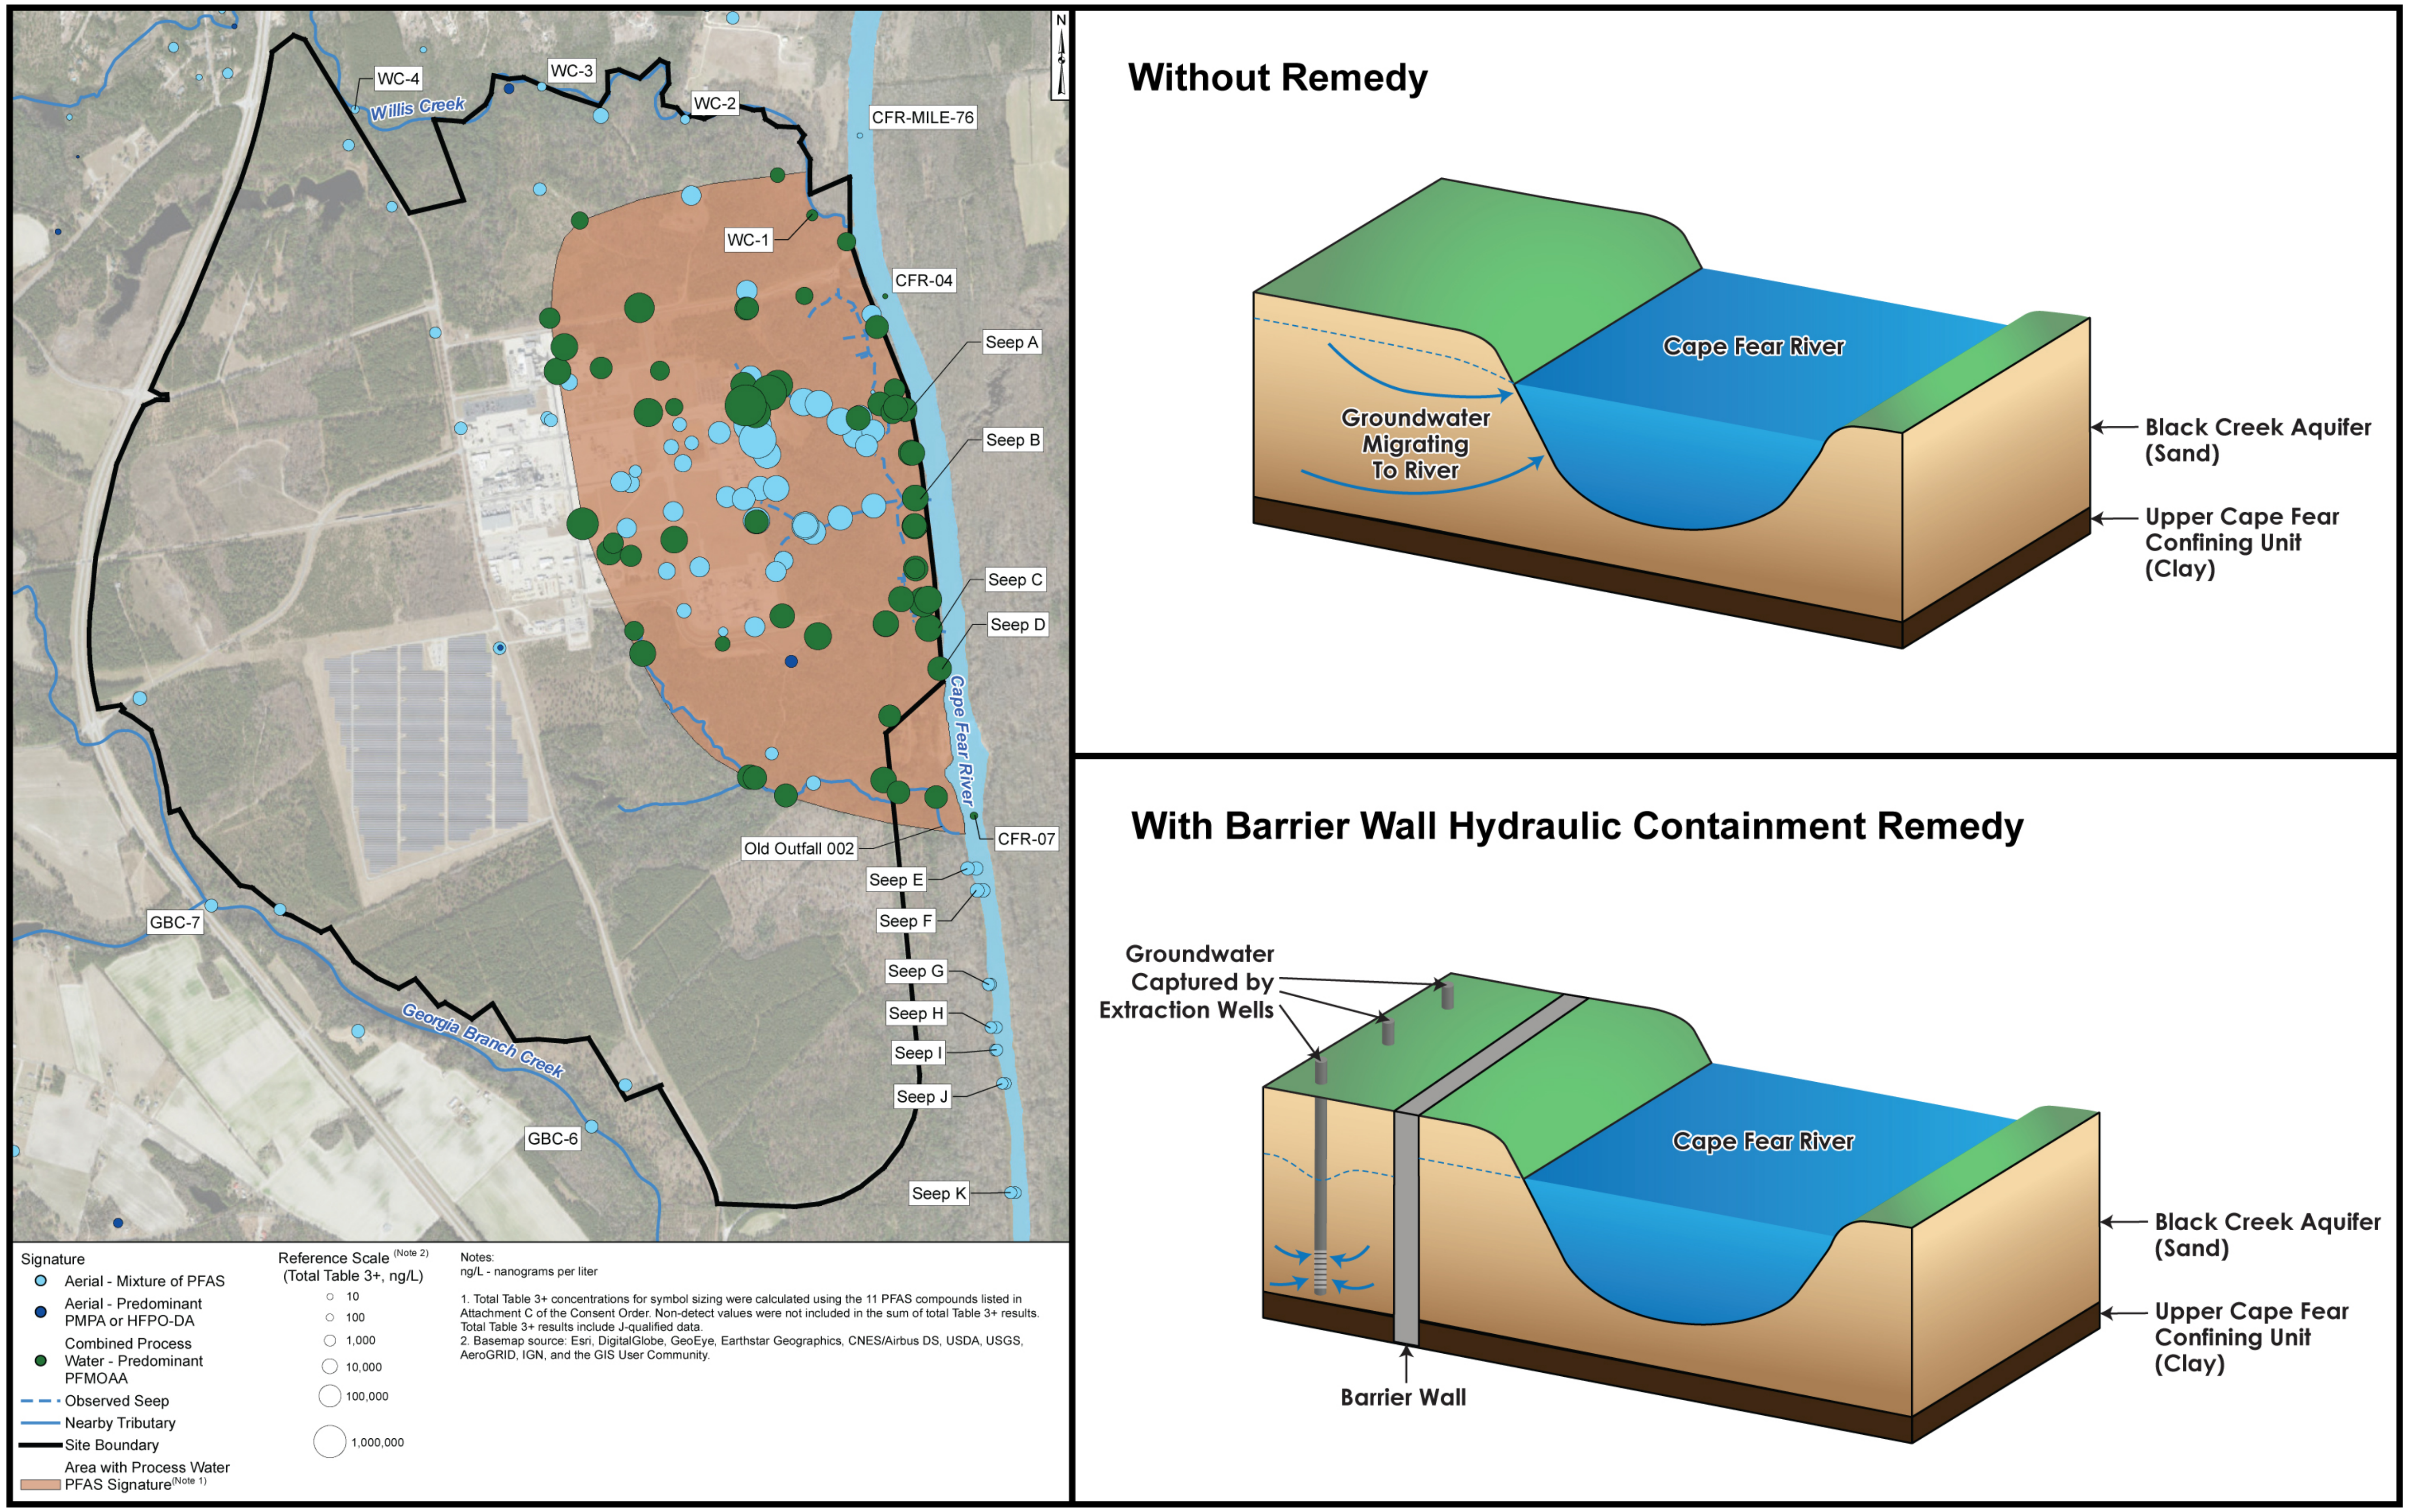

Figure 9: Area with Process Water PFAS Signature and Barrier Wall Conceptual Diagram

Cost

As discussed, many design details would still need to be determined, notably the barrier wall installation method (slurry wall vs. steel sheets), the most efficient method of incorporating flow into the Old Outfall 002 treatment system, and the exact alignment of the containment measures. For the purposes of this CAP, a low and high range cost were estimated as follows:

- Low Range: Slurry wall, with modular approach to incorporating flow into OOF2 treatment system (skid-mount systems installed with heat tracing, not within pre-fabricated building): The +50/-30% estimated construction cost is $19 to 41 million. The annual O&M cost is estimated to be $1.2 to 2.5 million. The 20-year NPV is estimated to be $36 to 77 million. Costing estimates are provided in Appendix I.
- High Range: Steel sheet pile wall, with pre-fabricated building to enclose the process equipment: The +50/-30% estimated construction cost is $34 to 74 million. The annual O&M cost is estimated to be $1.2 to 2.5 million. The 20-year NPV is estimated to be $51 to 110 million. Costing estimates are provided in Appendix I.

Path forward

The degree of PFAS loading that will be reduced by installation of the groundwater containment remedy described herein is uncertain, particularly its overall contribution to achieving a 75% Table 3+ PFAS loading reduction cost effectively. This remedy, if implemented, would reduce the PFAS loading to the river and, over time, reduce PFAS concentrations within the groundwater itself. On the other hand, the implementation of this remedy would be very costly and disruptive to the local ecological habitats.

The environmental benefits that would be realized from this remedy are at this point somewhat uncertain and based on data that have been limited by the short time frame in which the data needed to be assembled. For example, the September 2019 data show that the contributions to surface water loadings from this source may be as low as 14% of the total remaining loadings and are significantly less than the loadings from the two larger sources: groundwater seeps and Old Outfall 002. The September 2019 data show that those two sources alone could be up to 69% of the total remaining loadings. Yet, while the loadings from onsite groundwater may be only about a fifth of those for the top two sources, the costs to address onsite groundwater (see Appendix I) could be one and a half times as much as the total remedial costs for the groundwater seeps and Old Outfall 002.

With the information in hand, it is not presently possible to conclude with confidence whether this alternative is economically feasible. Accordingly, subject to DEQ approval, the best course of action is to proceed with the interim groundwater remedy described in Section, and at the same time proceed with a detailed pre-design investigation, a detailed remedy design and continued evaluation of PFAS mass loading to the Cape Fear River originating from the facility. This process of a pre-design investigation leading to a detailed design is consistent with prior remediation programs in North Carolina and the NCDEQ Guidelines (NCDEQ, 2017) that suggest CAPs include descriptions of "additional site characterization needed to support [the] proposed remedy".

Following an adaptive process allows the opportunity to further refine the understanding of PFAS mass loading from groundwater to the Cape Fear River, enabling a more detailed assessment of the technical and economic feasibility of the groundwater containment remedy. Additionally, this process will likely identify areas of higher PFAS mass discharge into the Cape Fear River from groundwater; and then remedial efforts can be focused to more expeditiously reduce loadings. Last, this process will enable adapting the scope and areas of groundwater treatment to reflect new information from other studies being conducted in support of the CO (e.g. total organic fluorine method development). Concurrent with the design effort, remedial alternative assessments will continue to evaluate the most cost-effective remedy that could achieve at least a 75% Table 3+ PFAS loading reduction and other CO objectives. The schedule for implementation of a groundwater remedy is included in Section 6.5 of this document; the pre-design investigation through detailed design and permitting is expected to take two years. At the conclusion of the effort, Chemours would present a detailed onsite remedial design to DEQ for approval.

6.3.5 Pathway: Outfall 002

Actions proposed for Outfall 002 in the previous Paragraph 12 submittals (i.e., the August 2019 Reduction Plan and the November 2019 Reduction Plan – Supplemental Information Report), which are summarized in Table 8 of Section 6, remain the same. The proposed path forward for the Outfall 002 remedies including the remedy descriptions, implementation schedules, and cost estimates can be accessed in the Supplemental Information Report (Geosyntec, 2019h).

6.3.6 Pathway: Loadings from Willis Creek and Georgia Branch Creek

While no offsite alternative was advanced for either creek, both creeks will over time have declining PFAS concentrations as a result of air control technology improvements that will reduce aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, with expected comparable reductions for other PFAS, leading to offsite aerial deposition reductions and consequently reductions over time in groundwater that discharges to these creeks. Additionally, were the onsite Black Creek aquifer groundwater extraction remedy to be implemented as conceptualized above, which would include approximately 2,100 linear feet of containment along the northeastern reach of Willis Creek that is in connection with the Black Creek aquifer, present estimates indicate the mass loading to Willis Creek may be reduced up to 65%, which in turn would reduce the mass loading to the Cape Fear River by approximately 3.7%.

6.3.7 Pathway: Offsite Groundwater

Offsite, PFAS have been aerially deposited and exist as a distributed, diffuse source potentially present over an area of at least 70+ square miles where concentrations in groundwater gradually become lower further away from the Site. Ongoing air abatement measures and the installation and operation of the thermal oxidizer will lead to a reduction of aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, and expected comparable reductions for other PFAS. Correspondingly, the deposition of PFAS to offsite soils will be reduced by 99% and over time concentrations will decline.

Mitigation measures for offsite water supply wells have been documented previously, including the On and Offsite Assessment (Geosyntec, 2019a). As discussed, pursuant to CO Paragraphs 19 to 25, Chemours is implementing a Drinking Water Compliance Plan (Parsons, 2019a). Through this plan, Chemours is providing replacement drinking water to private residents whose drinking water wells are impacted by PFAS listed on Attachment C of the CO. Replacement drinking water is being provided through a range of options depending on the levels of PFAS found. First residents are supplied bottled water as an interim measure. Then residents, should they accept, will receive either: (i) point of use reverse osmosis systems, (ii) whole house filtration systems, or (iii) connection to public water supplies. Pursuant to CO Paragraph 19, Chemours is working with NCDEQ to identify locations where public water is available and can be provided to private residents for less than $75,000 per affected party. Beyond this threshold, permanent water supplies will be provided through whole house filtration systems or reverse osmosis systems. Chemours is providing quarterly updates on implementation of the Drinking Water Compliance Plan to NCDEQ.

6.4 Proposed Remediation Permits

The thermal oxidizer, OOF2 treatment system, and sediment removal from the on-site non-contact cooling water (NCCW) and Outfall 002 activities are not discussed in this section as these remedies are already in the process of design and permitting or have already been completed. The terracotta pipe decommissioning and mitigation of groundwater intrusion into Outfall 002 remedies are also not discussed, as permits are not anticipated to be required. This section focuses on potential permits that may be required to construct the proposed interim and long-term remedies for seeps, onsite groundwater, and onsite stormwater.

The potential construction of flow-through cells, French drains, and a sheet pile barrier wall would likely require a comprehensive permitting approach, as segmented disturbances to natural features are typically required to be consolidated:

- Section 404 of the Clean Water Act as administered by the USACE. For the construction of the instream structures of OOF2, in October 2019, the USACE approved a NWP 38 - Cleanup of Hazardous and Toxic Waste. For the proposed construction of flow-through cells, French drains, and onsite barrier wall, it is anticipated that the USACE would concur that the NWP 38 similarly applies. Engagement with USACE, including an onsite review, could be required.
- Section 401 water quality certification as administered by the NCDEQ Division of Water Resources (DWR). The proposed installation of the flow-through cells, French drains, and onsite barrier wall would likely result in a disturbance to wetlands and streambeds that requires engagement with DWR and possible mitigation credits. As above with USACE, an onsite review would likely be required.
- NPDES as administered by NCDEQ. It is not anticipated that a NPDES permit would be required for the flow-through cells, as there is no point of discharge; however, engagement with NCDEQ to confirm may be warranted. For the seep French drains and for the barrier wall groundwater extraction, it is anticipated that modification of the draft NPDES permit may be required to either expand the OOF2 treatment system to accommodate this additional flow, and/or to permit the construction of a new treatment system and outfall. As NCDEQ has expressed a preference for a single NPDES permit for the Site, continued engagement with this agency will be required.
- Erosion and Sediment Control as administered by NCDEQ. For the construction of the seep and groundwater remedies, notably for the barrier wall which would require approximately 10 acres of disturbance, a comprehensive Erosion and Sediment Control (E&SC) Plan would be required, prepared in accordance with the latest revision to the E&SC Planning and Design Manual from 2013.

In addition to the above list, well construction permits will be required to install the extraction and monitoring wells. Building permits could also potentially be required for electrical connections to new treatment systems, if constructed.

6.5 Proposed Remediation Schedule

Detailed schedules for the Seeps and Onsite Groundwater remedies are provided below in Table 12 and Table 13. Table 14 describes the estimated performance and tentative schedule for proposed interim remedies and initial conceptual designs for long-term remedial strategies as both are closely integrated.

Table 12: Schedule for Proposed Seep Actions

Task	Duration (months)	Year 1	Year 2	Year 3	Year 4	Year 5
Bench Scale Testing and Lab Analysis	2					
Design, Work Planning and Permitting (1)	2					
Agency Approvals (2)	6					
Clearing and Grubbing	1					
Access Road Construction	1					
Electrical Service	3					
Seep A Flow Through Cell Construction and Pilot	6					
Seep D French Drain Construction and Pilot	6					
Seeps B and C Flow Through Cells Construction	6					
Evaluation of Initial Performance at Seeps A - D	6					
Optimization/Replacement of Cells/Drains as Needed	12					
Ongoing Operations and Maintenance	12					

1- Permits include but may not be limited to 404, 401, NPDES, and E&SC

2 - Task timing is dependent upon agency approval timing

Table 13: Schedule for Proposed Groundwater Action

Task	Duration (months)	Year 1				Year 2				Year 3				Year 4				Year 5			
Interim - Design and Work Planning for Pumping from Existing MWs	3	■																			
Interim - Installation and Operation	9		■	■	■

OOF2 System Upgrade (5)	24											■	■	■	■	■	■	■	■		
Testing and Commissioning	6																			■	■

1- Permits anticipated to potentially include but may not be limited to 404, 401, NPDES, and E&SC

2 - Task timing is dependent upon agency approval timing

3 - As the design and permitting process is advanced, there will be ongoing evaluation of the economical and technological feasibility of this remedial alternative, including analysis of new information that may become available over the next two years including any regulatory or permitting requirements, toxicological information, and other information concerning the condition and uses of the Cape Fear River. At the end of this two year period, Chemours would proceed with implementing this project, unless subsequent information shows that it is infeasible or if a more cost-effective alternative is available, in which case Chemours would seek DEQ approval.

4 - Material and method installation to be determined after pre-design investigation and design.

5 - Potential schedule assumes groundwater is conveyed to existing OOF2 system location and treatment train is upgraded to incorporate flow.

Table 14: Overall Estimated Reductions Plan Schedule and Reductions to Cape Fear River Total Table 3+ PFAS Loadings

Proposed and Provisional Remedial Alternatives	Loading Reduction	Duration (Years)	Year					
			2019	2020	2021	2022	2023	2024
Air Abatement Controls and Thermal Oxidizer[1]	<2%	1	✓					
Conveyance Network Sediment Removal - Outfall 002[2]	NQ[3]	1	✓

Groundwater Intrusion Mitigation - Outfall 002	0.7%	2						
Interim Action - CFR Seeps	NQ[3]	2						
Interim Action - Onsite Groundwater	NQ[3]	1						
Targeted Stormwater Control - Outfall 002	1.3%	4						
Ex Situ Capture and Treatment - CFR Seeps[4]	33%	4						
Onsite Groundwater Treatment	18%	5						
Cumulative Estimated Total Table 3+ PFAS River Reductions to River[5]	79%	--	<2%	26%	27%	43%	60%	79%

Notes

- Schedule for multiple alternatives are dependent upon permitting requirements.
- Loading reductions to CFR based on average of May, June, Sep. 2019 data
- Duration listed for implementation

1 - Scheduled implementation is December 31, 2019.
2 - Completed October 2019.
3 - Anticipated reduction from action cannot be quantified at present.
4 - Assumed to be Ex Situ Capture as the permanent remedial alternative for seeps.
5 - Cumulative estimated reductions assumes:
a) that reductions are achieved at the end of the implementation period; and
b) that the time period for contingent actions is not needed.

7 PERFORMANCE MONITORING

This section describes performance monitoring activities to accomplish the following objectives:

a) Corrective action performance monitoring;
b) Compliance with CO paragraph 16(d) performance monitoring;
c) On and Offsite groundwater quality monitoring.

The monitoring activities for objectives listed above are described in the following sections. These monitoring activities were developed concurrently with the CAP and may evolve during the course of pre-design investigations, pilot tests, preliminary results or other conditions. Monitoring locations, frequency and number of samples, analytical list and methods presented here may be modified to achieve objectives. Any potential recommended modifications to the monitoring plan will be presented in semi-annual monitoring data reports.

7.1 Corrective Action Performance Monitoring

Overall, the collective performance of the corrective actions will be assessed through PFAS mass loading reductions to the Cape Fear River as described in Sections 7.2 and 7.3 for Objectives (b) and (c) listed above. Individually the performance of corrective actions will be evaluated for both interim and long-term corrective actions proposed here and identified in the Reduction Plan Supplemental Information Report (Geosyntec, 2019h). Performance monitoring activities are described below for the following actions:

- Old Outfall 002
- Onsite Groundwater Seeps Interim Actions
  - Flow Through Cells
  - Capture and Treat (French Drains)
- Onsite Seeps Long-Term Actions
- Onsite Groundwater Interim Actions
- Onsite Groundwater Long-Term Actions

7.1.1 Old Outfall 002 Capture and Treatment Performance Monitoring

As required by the CO baseline surface water samples were collected from Old Outfall 002 for a six month period between March and August 2019 at locations indicated in Attachment A of the CO and analyzed for Table 3+ SOP and Modified EPA Method 537 compounds listed in Table 2. Performance monitoring for the treatment system will be performed according to the terms of the NPDES permit which in late 2019 had not yet been issued by NCDEQ.

7.1.2 Onsite Groundwater Seeps Interim Actions

Interim actions for groundwater Seeps A, B, C and D reaching the Cape Fear River at the Site include combination of flow-through cells and ex situ capture using French drains (Geosyntec, 2019h). The flow-through cell interim actions are proposed to start at Seep A with implementation progressing successively through Seeps B and C where lessons learned from the construction and operation of the flow-through cells at the prior seeps would be used to design and operate the subsequent flow-through cells. An ex-situ capture French drain would be installed at Seep D. A six-month pilot for both interim actions is recommended, followed by implementation of interim seep actions for a period of two years during which time the performance of each approach will be monitored and optimized. Operational and performance monitoring during pilot testing will be documented in pilot testing workplans. Monitoring efforts proposed during the two-year interim action implementation period are discussed below.

Flow-through cells

Visual inspections of flow-through cells will be performed to document and check the integrity and operation of the flow-through cell. Inspections shall be performed periodically or when circumstances beyond design limitations arise (e.g., excessive rainfall and flooding). Necessary repairs for continued operation and maintenance shall be documented including system down time, repairs/changes performed and other pertinent observations to operation of flow-through cell.

Table 3+ PFAS removal efficiency of the flow-through cell will be monitored by mass flux upstream and downstream of the cell. Mass flux will be measured by measuring flow and PFAS concentrations in surface water before it flows into the flow through structure and after it flows out. Flow rate measurement methods will be finalized following pre-design investigations. Performance sampling frequency is assumed to be at minimum quarterly during the start-up operational period of the flow-through cell. Spatial density and sampling frequency may be amended during pilot testing or under special circumstances including repair/carbon change out, flooding, etc.

Seep capture and ex situ treatment

Visual inspections of seep capture will be performed to evaluate the integrity and operation of the French drains periodically or when circumstances beyond design limitations arise. Necessary repairs for continued operation and maintenance shall be documented including system down time, repairs/changes performed and other pertinent observations to continued operation.

Capture efficiency of the seep capture remedy shall be assessed by monitoring influent seep flow rate, water levels in catchment basin and vertical sump and measuring sump pump rate. Treatment efficiency for this remedy is continuous operation of the collection pumps and the performance and proper operation of the treatment plant utilized. If flowing surface water is visibly expressed downgradient of the remedial system, samples may be collected for and analyzed for Table 3+ PFAS.

7.1.3 Onsite Groundwater Seeps Interim Actions

Based on operational and performance success one of the two interim remedial actions will be implemented at the Seeps as a long-term remedy (Geosyntec, 2019h). Operational and performance monitoring metrics identified for the interim actions are planned to be included in the long-term monitoring plan. Additional metrics identified during the interim operational period may be added to the long-term monitoring plan along with optimizing spatial density and temporal frequency of sampling. For the purpose of this plan, it is assumed that quarterly performance monitoring events will take place for the first two years of implementation followed by an optimization monitoring plan, which will be documented in monitoring data reports.

7.1.4 Onsite Groundwater Interim Actions

As an interim action groundwater will be extracted from seven existing onsite wells until a long-term remedy is operational unless otherwise improved, modified or demonstrated to be ineffective by subsequent analyses or evaluations. Periodic water levels will be collected from adjacent and surrounding monitoring wells to gauge a capture zone. Pumping rates will be periodically documented along with flow rate measurements in the conveyance piping to the treatment plant utilized. Treatment efficiency for this remedy is continuous operation of the collection pumps and the performance and proper operation of the treatment plant.

7.1.5 Onsite Groundwater Long-Term Remedial Actions

Monitoring actions presented here are preliminary pending pre-design investigations, pilot testing, final design, preliminary results and operational metrics or other conditions as described in Section 6.3.4. Monitoring locations and frequency and number of samples presented here may be modified to achieve the overall monitoring plan objectives.

Visual inspections of extraction wells, piping and other pertinent components will periodically be inspected to document and check the integrity and operation of the system or when circumstances beyond design limitations arise (e.g., flooding). Necessary repairs for continued operation and maintenance shall be documented including system down time, repairs/changes performed and other pertinent observations to operation of the system.

The effectiveness of the long-term groundwater remedial action will be assessed through water level measurement conducted with transducers in a network of extraction wells and monitoring wells. Transducer monitoring may also be periodically supplemented with manual water levels from representative wells in target aquifers. Water level data will be used to monitor temporal and spatial variations in hydraulic gradient magnitudes and direction to demonstrate hydraulic containment. The list of wells, including addition of new wells, will be identified during pre-design investigations and design reports. Appropriate sampling phasing and frequency may be re-evaluated during system startup and equilibration or if circumstances beyond design limitations arise. If necessary, the numerical groundwater model may be employed to perform a flow path analysis using measured water levels with particle tracking to demonstrate hydraulic capture.

7.1.6 Replacement Drinking Water Supplies

CO Section F contains requirements for Replacement Drinking Water Supplies that Chemours has been complying with, including a comprehensive program for testing private wells near the facility. Paragraph 21 states that Chemours shall perform annual retesting of private wells and "request incorporation of a plan to carry out this requirement in its Corrective Action Plan." Chemours set forth its plan for annual retesting of private wells in its April 26, 2019 Drinking Water Compliance Plan and its August 22, 2019 response to DEQ's comments on the Drinking Water Compliance Plan. Chemours hereby requests incorporation of that annual retesting plan into the CAP.

7.2 Compliance with CO Paragraph 16(d) Performance Monitoring

CO Paragraph 16(d) requires that Chemours:

> *"reduce PFAS loading to surface water (Old Outfall 002, Willis Creek, Georgia Branch, and the Cape Fear River), for the PFAS for which test methods and lab standards have been developed, by at least 75% from baseline.*

This subsection describes the performance monitoring activities to develop the baseline and evaluate reductions from baseline consistent with CO paragraph 16(d) requirements.

The best available and most representative data will be used to develop the baseline and evaluate reductions performance. These data will include empirically measured flows and concentrations from PFAS transport pathways described in Section 3.10. These data will include measurements such as flow and concentrations of PFAS in the creeks and in the Cape Fear River in addition to contextual information from groundwater wells including concentrations and potentiometric surface. These data will produce direct measurements of PFAS mass loading in multiple pathways and more importantly in the Cape Fear River itself. These data will be interpreted in conjunction with the Cape Fear River PFAS Mass

Loading Model (Geosyntec, 2019g) to facilitate standardized comparisons of mass loading between monitoring events.

Based on analyses presented in Section 5.4 of this CAP and the Reductions Plan Supplemental Information Report, the proposed corrective actions are intended to reduce the combined total Table 3+ PFAS mass loading reaching surface waters by 75%. Monitoring activities outlined here focus on developing additional data for the baseline of Table 3+ PFAS mass loadings to the Cape Fear River and evaluating the 75% reductions of PFAS mass loads in the Cape Fear River. While the mass loads in the other surface water bodies will be measured, only the Cape Fear River will be evaluated against 75% reductions for the following four reasons. First, all the Table 3+ PFAS mass loading to these surface waters reaches the Cape Fear River, and therefore it is a natural monitoring end point. Second, the Cape Fear River is the only surface water body listed in paragraph 16(d) that is used as a raw water intake. Third, both the human health and ecological SLEAs determined there were no presently identifiable hazards or adverse effects from HFPO-DA exposures on and offsite, including from surrounding surface waters. And fourth, as described in the Reduction Plan Supplemental Information report, reducing PFAS loading to Georgia Branch Creek and Willis Creek by over 75%, or in any other material way in the short term, is economically infeasible and technically challenging to infeasible.

The following two subsections describe how the baseline will be established and how performance monitoring towards the 75% Table 3+ PFAS mass loading reduction will be conducted.

7.2.1 Paragraph 16(d) Baseline Monitoring

The baseline monitoring program will collect additional data on flow rates and PFAS concentrations from the various potential PFAS transport pathways to the Cape Fear River, as identified in the mass loading model assessment (Geosyntec, 2019g). Specifically, Table 15 below lists transport pathways and sampling locations for where data will be collected:

The locations in the table above supplement and improve the ability to measure the PFAS mass loading baseline as described in Paragraph 16(c) of the CO:

> *"The baseline will be established using the average of the concentrations of the PFAS in groundwater monitoring wells for each surface water and LTWs along the Cape Fear River over the first four (4) quarters of sampling."*

Table 15: Baseline and Groundwater Monitoring Locations

Transport Pathway	Concentration	Flow
Willis Creek	✓	✓
Seep A	✓	✓
Seep B	✓	✓
Seep C	✓	✓
Seep D	✓	✓
Outfall 002	✓	✓
Old Outfall 002	✓	✓
Georgia Branch Creek	✓	✓
Groundwater Wells	✓	Water Levels
Cape Fear River	✓	✓

Paragraph 16(c) requires groundwater wells adjacent to Willis Creek, Old Outfall 002, Georgia Branch Creek and the Cape Fear River to facilitate developing baseline Table 3+ PFAS loadings. These wells already exist. Some of these wells pre-existed the CO and some were installed in 2019 as part of the onsite and offsite characterization programs. All the identified wells are listed in Table 16 and are adjacent to surface water bodies to fulfill paragraph 16(c) and (d) requirements. In total 22 monitoring wells, including the five LTW wells, will be monitored as part of the baseline monitoring activities. These wells are listed in Table 16 and shown on Figure 10.

Should interim or long-term corrective actions be complete at Groundwater Seeps, Old Outfall 002, or some other PFAS loading pathway before the additional monitoring data collection is complete, then the pre-treatment mass loading and/or collected Site data will be used to establish the baseline mass load. For instance, if the Old Outfall 002 treatment system is operational and removes 99% of all Table 3+ PFAS compounds, then the adjusted baseline mass loading in the river may be calculated as the measured mass loading in the river (river flow multiplied by river concentrations) plus the mass removed by the Old Outfall 002 treatment system (influent mass loading minus effluent mass loading).

The list of monitoring wells identified here, the temporal frequency of sampling, and the list of PFAS compounds analyzed, may evolve during the course of pre-design investigations, pilot tests, preliminary results or other conditions as necessary for developing the baseline. Any changes will be described, along with the rationale for the change in subsequent monitoring reports submitted to NCDEQ.

The baseline monitoring program will be completed over four quarters of sampling. After the data are received for each the first three quarters a quarterly baseline monitoring report will be prepared. After the fourth quarter of monitoring is complete a baseline monitoring report outlining the results of the program will be prepared.

The sampling activities for the first quarter of monitoring were completed between November and December 2019. Flow gauging and surface water sampling was conducted in November 2019; groundwater levels and samples were collected in December 2019. The first baseline quarterly reports will be prepared and submitted to NCDEQ in first quarter 2020.

Last, to develop a more continuous record of Table 3+ PFAS mass loading into the Cape Fear River, a pilot program will be undertaken and will be include collecting composite samples from the Cape Fear River downstream of the facility where the Cape Fear River is well mixed – about 5 miles downstream, provided required access agreements, etc., can be negotiated. These samples will enable a more consistent and continuous record of baseline Table 3+ PFAS mass loads in the Cape Fear River. Additionally, as composite samples, these samples will help attenuate the potential inherent natural variability possible when collecting and measuring samples in the Cape Fear River, a complex and dynamic system.

Table 16: Baseline Monitoring Well Locations

List Number	Well ID	Adjacent Surface Water Feature	Hydrogeological Unit
1	PIW-3D	Cape Fear River	Black Creek
2	PIW-7S	Cape Fear River	Floodplain
3	PIW-7D	Cape Fear River	Black Creek
4	LTW-01	Cape Fear River	Floodplain
5	LTW-02	Cape Fear River	Black Creek
6	LTW-03	Cape Fear River	Floodplain
7	LTW-04	Cape Fear River	Floodplain
8	LTW-05	Cape Fear River	Black Creek
9	PZ-22	Cape Fear River	Black Creek
10	PW-06	Georgia Branch Creek	Surficial
11	PW-07	Georgia Branch Creek	Surficial
12	PW-04	Old Outfall	Surficial
13	PW-11	Old Outfall	Black Creek
14	PW-09	Willis Creek	Black Creek
15	SMW-11	Willis Creek	Surficial
16	SMW-10	Willis Creek	Surficial
17	INSITU-02	Willis Creek	Surficial
18	SMW-12	Willis Creek	Black Creek
19	PIW-1S	Cape Fear River / Willis Creek	Floodplain
20	PIW-1D	Cape Fear River / Willis Creek	Surficial
21	Bladen-1S	Georgia Branch Creek	Surficial
22	Bladen-1D	Georgia Branch Creek	Black Creek

Notes:
1. Hydrogeologic units for existing wells determined based on boring log descriptions.
2. Samples to be collected quarterly, starting December 2019 through December 2020.
3. All samples to be analyzed for Table 3+ and Modified EPA Method 537.

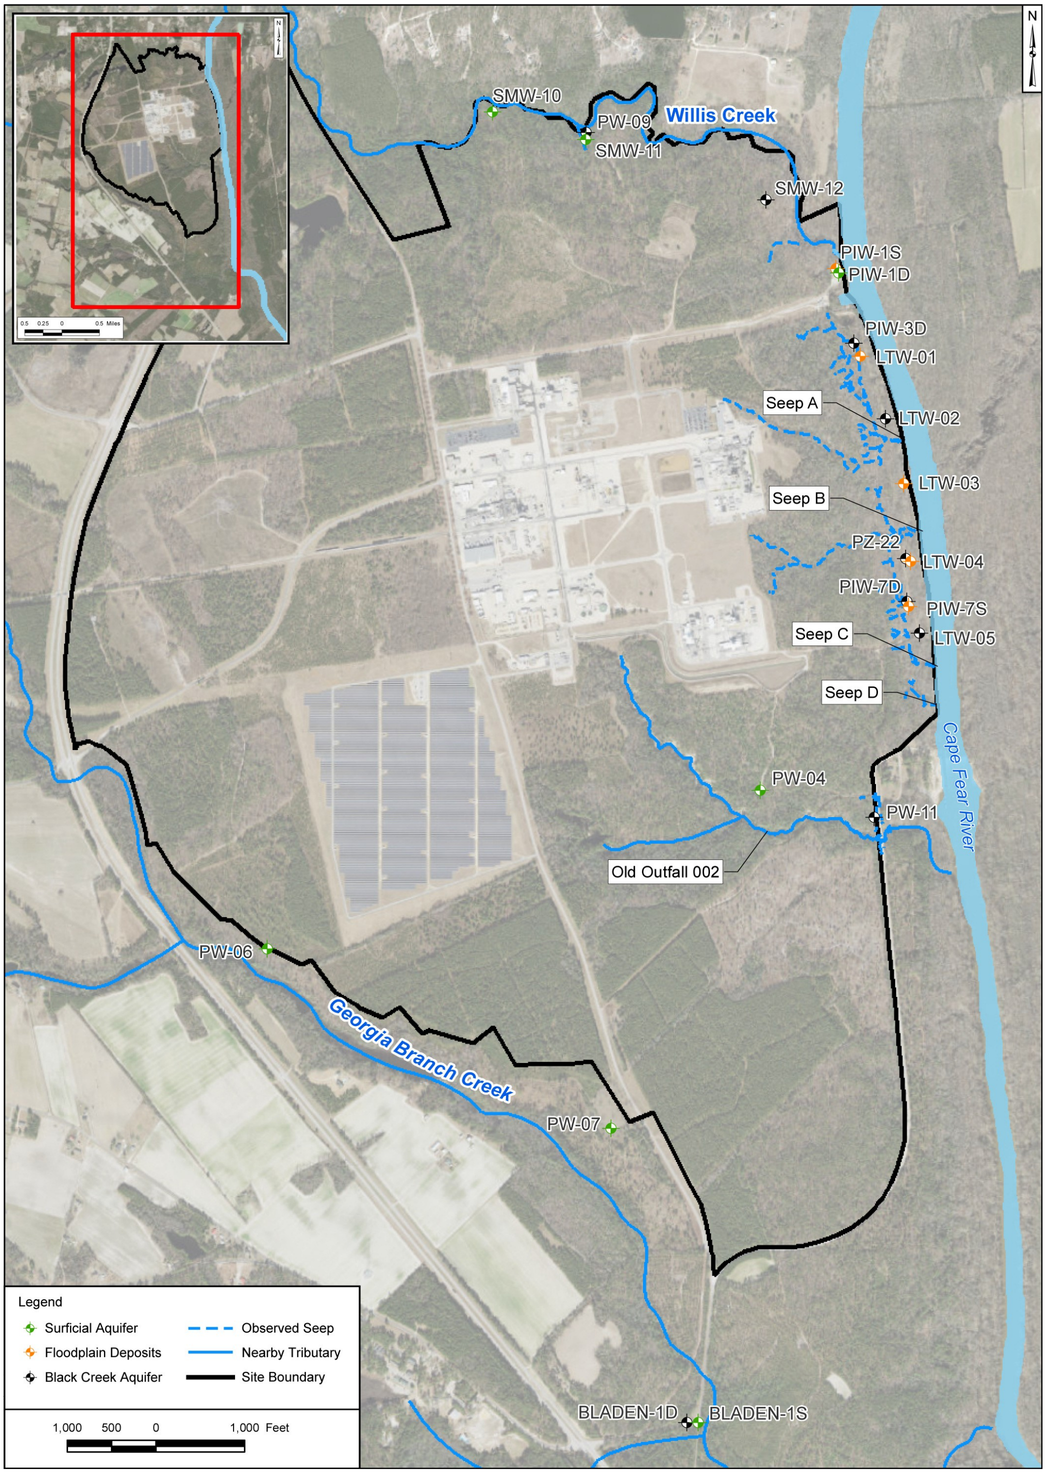

Figure 10: Baseline Monitoring Well Locations

7.2.2 Paragraph 16(d) Reductions Monitoring

Reductions in Table 3+ PFAS mass loading to the Cape Fear River will be evaluated relative to the baseline Table 3+ PFAS mass loading that will be developed during the baseline program. The reductions in the river Table 3+ PFAS loadings will be evaluated using the same set of monitoring locations identified for the baseline loading development. Potential adjustments to the reductions monitoring plan to increase its effectiveness will be outlined in the baseline monitoring report based on observations and outcomes from baseline monitoring.

A 75% reduction in Table 3+ PFAS mass loading to the Cape Fear River will be considered achieved when eight successive quarters of data show a 75% decrease in PFAS mass loads measured in the Cape Fear River. Consistent with CO paragraph 16(d) this observation will be supported using by (a) performance monitoring of the corrective actions showing successful reductions in concentrations, (b) measurements of loadings from the various PFAS transport pathways, and (c) evidence of reduction in groundwater PFAS mass loading to the Cape Fear River based on concentrations in LTW and the other groundwater wells and the groundwater gradients used to calculate flows to the surface water bodies and the Cape Fear River.

7.3 Onsite and Offsite Groundwater Quality Monitoring

Starting in 2020 in addition to the 22 wells being monitored quarterly as part of the paragraph 16(d) baseline and reduction monitoring programs, onsite and offsite wells installed by Chemours will be sampled annually between July 1st and September 30th (third quarter) for a period of three years. By March 31st each year a groundwater monitoring report will be prepared describing the results of the sampling from the prior year. After three years of sampling, the third annual groundwater monitoring report will evaluate if changes should be made to the sampling program such as reducing the number of wells sampled or abandoning certain wells. Some of the present wells at Site may be abandoned due to either construction issues or consistently dry wells screens before this sampling program is implemented.

Offsite private wells are presently being sampled on a routine bases as defined in the Drinking Water Compliance Plan (Parsons, 2019a).

8.1	8.1	34.85494	-78.83748	59	Black Creek Confining Unit	Creek bed	1	gray/black clay	NA	NM	NM	NM	Dark gray, massive clay in creek bed.
8.2	8.2	34.85515	-78.83779	55	Black Creek Confining Unit	Creek bed		gray/black clay	NA	NM	NM	NM	Dark gray, massive clay in creek bed.
9	9.1	34.83764	-78.83535	120	Perched Aquifer	Stream Cut Wall	1	sand	clay	81	7	Bedding	Reddish tan, fine- to medium-grained sand with 1 foot thick interbedded dark gray clay layer.
10	10.1	34.83678	-78.83484	105	Perched Clay	Stream Cut Wall	4	clay	NA	52	5	Bedding	Dark gray, thinly bedded clay with trace mica. First clay exposure since last station.
11	11.1	34.83559	-78.83350	90	Perched Clay	Stream Cut Wall	1.5	clay	NA	42	7	Bedding	Light gray (top 6 inches) and dark gray, fat clay. Lithology is similar to station 10.1 and 11.1.

TABLE A 6-1
SUMMARY OF FINDINGS OF GEOLOGIC MAPPING STUDY
Chemours Fayetteville Works, North Carolina

Map ID	Station ID	Latitude	Longitude	Estimated Elevation (ft NAVD 88)	Unit	Outcrop Type	Thickness (ft)	Major Lithology	Minor Lithology	Strike	Dip	Type	Notes
12	12.1	34.83540	-78.83321	89	Perched Clay	Stream Cut Wall	3.25	clay	NA	8	8	Bedding	Light gray (top 6 inches) and dark gray, fat clay. Lithology is similar to station 10.1.
13	13.1	34.83465	-78.83266	98	Surficial Aquifer	Stream Cut Wall	6.5	silty clay	NA	0	0	Bedding	Dark gray clay with silt component. Top 6 inches of outcrop is highly oxidized. Burrows observed.
14	14.1**	34.83402	-78.83176	78	Surficial Aquifer	Stream Cut Wall	5	organic rich silt	NA	0	0	Bedding	Dark black, lignite-rich silt with trace clay.
	14.2**						1.5	claystone	NA	NM	NM	NM	Interlayered dark and light gray clay. Station was observed across stream from station 14.1, approximately 15 to 20 feet below elevation of 14.1.
15	15.1	34.83339	-78.83075	77	Surficial Aquifer	Stream Cut Wall	4	sand	clay	NM	NM	NM	White, poorly graded sand with cm- to mm-scale interlayers of black clay.
16	16.1	34.83320	-78.83058	81	Black Creek Confining Unit	Stream Cut Wall	7	clay	sand	19	7	Bedding	Fat dark gray clay with mm- to cm-scale interlayers of sand. First large exposure of clay since 12.1 and 13.1. Appears to begin approximately 30 feet upstream of this station.
17	17.1*	34.83308	-78.83014	82	Black Creek Confining Unit	Stream Cut Wall	17	clay	NA	0	0	Bedding	Dark gray, thinly bedded to massive clay with local oxidized surficial staining.
	17.2*									7	85	Joint	
18	18.1	34.83301	-78.82951	81	Black Creek Confining Unit	Stream Cut Wall	10	clay	NA	0	0	Bedding	Light and dark gray, thinly bedded clay with local surficial staining.
19	19.1	34.83316	-78.82911	81	Black Creek Confining Unit	Stream Cut Wall	2	clay	NA	0	0	Bedding	Dark gray, thinly bedded clay.
20	20.1	34.83264	-78.82603	67	Black Creek Confining Unit	Stream Cut Wall		gray clay	NA	NM	NM	NM	Unable to access outcrop but appears to be dark gray, fat clay.
21	21.1	34.83292	-78.82626	69	Black Creek Confining Unit	Stream Cut Wall		light gray clay	NA	0	0	Bedding	Gray, fat clay and interbedded sand with trace mica and lignite chips. Pieces of petrified wood observed upstream.
22	22.1	34.83335	-78.82749	73	Black Creek Confining Unit	Stream Cut Wall		light gray clay	NA	0	0	Bedding	Light gray clay and interbedded fine-grained, angular sand with abundant lignite chips.
23	23.1*	34.83355	-78.82854	73	Black Creek Confining Unit	Stream Cut Wall	15-20	light to dark gray clay	NA	0	0	Bedding	Light to dark gray clay. Appears to be continuous from station 23.1. Multiple joint sets observed that show surficial weathering and horizontal bedding.
	23.2*									37	82	Joint	
	23.3*									320	89	Joint	

TABLE A 6-1
SUMMARY OF FINDINGS OF GEOLOGIC MAPPING STUDY
Chemours Fayetteville Works, North Carolina

Map ID	Station ID	Latitude	Longitude	Estimated Elevation (ft NAVD 88)	Unit	Outcrop Type	Thickness (ft)	Major Lithology	Minor Lithology	Strike	Dip	Type	Notes
24	24.1	34.83299	-78.82963	82	Black Creek Confining Unit	Stream Cut Wall		dark gray clay	NA	0	0	Bedding	Dark clay and interbedded fine-grained sand.
25	25.1	34.83689	-78.82464	61	Black Creek Confining Unit	NR	2	clay	NA	239	11	Bedding	Dark gray, thinly bedded clay. Identified as Seep D-D1 in Seep Investigation.
26	26.1	34.84158	-78.82854	99	Perched Clay	Waterfall	2	clay	NA	210	10	Bedding	Dark gray with orange surficial staining, thinly bedded to massive clay. First observed outcrop of clay in seep B.
27	27.1	34.84175	-78.82720	81	Black Creek Confining Unit	Ledge	2.5	clay	NA	NM	NM	NM	Gray, massive, fat clay. Large petrified boulder observed.
28	28.1*	34.84184	-78.82665	75	Black Creek Confining Unit	Waterfall	10	clay	NA	238	19	Bedding	Waterfall outcrop of dark gray, thinly bedded clay and interbedded fine-grained sand.
	28.2*									115	23	Bedding	
	28.3*									265	87	Joint	
29	29.1	34.84415	-78.82675	67	Black Creek Confining Unit	NR	2	clay	NA	224	9	Bedding	Dark gray, massive, lean clay, with iron-oxide surficial staining and small 1cm-scale interbedded sand laminations. First exposure observed on seep A. Seep A-6, A-1
30	30.1	34.84442	-78.82971	147	Perched Aquifer	NR		unconsolidated sand	clay	NM	NM	NM	Tan brown, fine- to medium-grained, unconsolidated sand. Identified as Seep A-7-B1 in Seep Investigation.
31	31.1	34.84424	-78.82683	68	Black Creek Confining Unit	NR	1		NA	0	0	Bedding	Dark gray clay with horizontal bedding. Identified as Seep A8 in Seep Investigation.
32	32.1	34.84505	-78.82794	99	Surficial Aquifer	NR	1	clayey sand	NA	NM	NM	NM	Red-brown, massive clayey sand with nodules of claystone and siltstone in dry creek bed.
33	33.1	34.84519	-78.82806	103	Surficial Aquifer	NR	4	sand	NA	NM	NM	NM	Red-brown, moist, fine- to coarse-grained sand with gravel sized quartz grains. Identified as Seep A-10.
34	34.1	34.84543	-78.82876	125	Perched Clay	NR	2-3	clay	NA	87	8	Bedding	Red-brown and orange, moist clay with interlayers of medium-grained sand.
35	35.1	34.84575	-78.82959	136	Perched Clay	NR	1	clay	sand	269	8		Reddish gray, clay overlying orange, medium- to coarse grained, hematite-rich sand and interbedded clay.
36	36.1	34.84860	-78.82790	62	Black Creek Confining Unit	NR	4	petrified wood	NA	NM	NM	NM	4 foot in diameter, petrified tree trunk and dark red to gray, massive fat clay. Identified as Seep A-5.

TABLE A 6-1
SUMMARY OF FINDINGS OF GEOLOGIC MAPPING STUDY
Chemours Fayetteville Works, North Carolina

Map ID	Station ID	Latitude	Longitude	Estimated Elevation (ft NAVD 88)	Unit	Outcrop Type	Thickness (ft)	Major Lithology	Minor Lithology	Strike	Dip	Type	Notes
37	37.1	34.84860	-78.82799	65	Black Creek Confining Unit	NR	0.5	clay	NA	NM	NM	NM	Dark red to gray, massive, fat clay.
38	38.1	32.84858	-78.82819	72	Black Creek Confining Unit	NR	6-7	clay	NA	NM	NM	NM	Dark to light gray, intricately layer/interbedded clay and fine- to medium-grained sand.
39	39.1	34.85524	-78.83652	53	Black Creek Confining Unit	NR	10	clay	NA	352	46	Joint	Light to dark gray clay with cm-scale, fine-grained sand lenses throughout with local lignite layers. Outcrop is approximately 100 feet in length.
40	40.1	34.85582	-78.83624	54	Black Creek Confining Unit	NR	3.5	clay	NA	0	0	Bedding	Light to dark gray clay with cm-scale, fine-grained sand lenses throughout with local lignite layers. Outcrop is approximately 70 feet in length.
41	41.1	34.85572	-78.83624	53	Black Creek Confining Unit	NR	10	clay	NA	0	0		Light to dark gray clay with cm-scale, fine-grained sand lenses throughout with local lignite layers. Outcrop is approximately 50 feet in length.

Notes:
1. * indicates multiple station ID's at the same outcrop.
2. ** indicates station locations at different outcrops but within the same vicinity.
3. Latitude and longitude were measured by Parson's field staff using Arc Collector in conjuction with the Garmin Glow GPS.
4. Elevations were estimated from 2018 USGS topographic map.
5. ft above MSL - feet above mean sea level.
6. Strikes and dips were measured using a Brunton compass.
7. Seep ID's are referenced from Geosyntec 2019, *Seeps and Creeks Investigation Report.* Chemours Fayetteville Works. 26 August 2019.
8. Soil classification are based off of Unified Soil Classification System

ft - feet

Notes:

1. Locations for HPT borings (HP-1 through HP-32) were not surveyed and are approximate. PIW-soil boring locations reported correspond to surveyed co-ordinates for a shallow well location where a shallow and a deep well were co-located. PIW-well locations are provided in Table 5.
2. Ground surface elevations for HPT borings are estimated from LIDAR ground surface elevations. LIDAR ground surface elevation from 20-Foot DEM Elevation Service collected by NC Floodplain Mapping Program and processed by NC DOT - GIS Unit.Service URL:https://services.nconemap.gov/secure/rest/services/Elevation/DEM20ft_DEM/ImageServer last accessed 6-19-2019 23:24
3. Ground surface elevations for PIW-soil borings correspond to surveyed co-ordinates for a shallow well location where a shallow and a deep well were co-located. PIW-well ground surface elevations are provided in Table 6-3.
4. LIDAR estimated ground surface elevations underestimate surveyed ground surface elevations by 0.4 - 1.0 feet.

ft bgs - feet below ground surface
ft - feet

Notes:
1. Survey completed by Freeland-Clinkscales & Associates of NC.
2. Northing and Easting provided in feet, State Plane Coordinates for North Carolina (zone 3200) in North American Datum of 1983.
3. Ground surface and top of casing elevation reported in North American Vertical Datum of 1988.
ft NAD83 - feet, State Plane Coordinate System North American Datum 1983
ft NAVD88 - feet, North American Vertical Datum of 1988
in - inches
ft - feet
ft bgs - feet below ground surface
NA - not available
NM - not measured

TABLE A 6-4
SUMMARY OF ESTIMATED HYDRAULIC CONDUCTIVITY
Chemours Fayetteville Works, North Carolina

Hydrogeologic Zone	Geometric Mean Hydraulic Conductivity, K		
	K (cm/s)	**K (ft/d)**	**Wells Included**
Floodplain Deposits	3.23×10^{-4}	0.9	LTW-01 [4], LTW-03 [4]
Black Creek Aquifer	9.89×10^{-3}	28.0	SMW-12, LTW-02, BCA-02, BCA-04, BCA-01
Partially Screened across Floodplain and Black Creek Aquifer	1.86×10^{-3}	5.3	LTW-05

Notes:

1. Detailed slug test results, AQTESOLV inputs, displacement time curves and AQTESOLV outputs used to summarize results are included in Appendix E.

2. Geometric means calculated from both pneumatic and manual slug test results. No method bias was observed. Pneumatic slug tests were performed only at locations where well screen was fully saturated. Manual slug tests were performed at all other well locations.
3. LTW-04 results not included in calculating geometric mean because initial displacement for all tests at this well suspected to display oscillatory response likely due to inertial effects from water table across well screen.
4. Initial displacement response curve suspected to display double-straight line effect due to drainage from filter pack. Analytical solutions are fit to the second-straight line displacement curve representing post-filter drainage, aquifer response.

cm/s - centimeters per second

ft/d - indicates feet per day

K - hydraulic conductivity

Notes:

1. * PW-10 was properly abandoned and replaced with PW-10R.
2. "USCS Classification" is the Unified Soil Classification System from the standard practice outlined in ASTM D2487-17.
3. Coefficient of Uniformity (C_u) = D_{60} / D_{10}
4. Coefficient of Curvature (C_c) = $(D_{30})^2$ / (D_{60} * D_{10})
5. Hydraulic Conductivity (K) from grain size calculated using HydrogeoSieveXL (Devlin, 2015).
6. Atterberg limits (Liquid Limit and Plastic Limit) are only tested for fine-grained materials.
7. Visual descriptions are transcribed from field logs.
8. USCS classifications are derived from laboratory data.

-- not measured
% - percent
cc - cubic centimeter
CH - fat clay
CL - lean clay
ft bgs - feet below ground surface
ft/d - feet per day
g - gram
NP - no plasticity
SC - clayey sand
SM - silty sand
SP - poorly graded sand
GP - poorly graded gravel
SW - well graded sand
USCS - Unified Soil Classification System

Notes:

1. Laboratory results available as of 09/24/2019 are reported. Additional data will be presented in an addendum to this report.
2. "USCS Classification" is the Unified Soil Classification System from the standard practice outlined in ASTM D2487-17.
3. Coefficient of Uniformity (C_u) = D_{60} / D_{10}
4. Coefficient of Curvature (C_c) = $(D_{30})^2$ / (D_{60} * D_{10})
5. Hydraulic Conductivity (K) from grain size calculated using HydrogeoSieveXL (Devlin, 2015).
6. Atterberg limits (Liquid Limit and Plastic Limit) are only tested for fine-grained materials.
7. Visual descriptions are transcribed from field logs.
8. USCS classifications are derived from laboratory data.

-- not measured
% - percent
cc - cubic centimeter
NP - no plasticity

N-methyl perfluoro-1-octanesulfonamide	--	--	--	--

Notes:
1. Associated soil analytical results reported in Table 7-5.
Bold - Analyte detected above associated reporting limit
EPA - Environmental Protection Agency
ft - feet
ng/L - nanograms per liter
QA/QC - Quality assurance/ quality control
SDG - Sample Delivery Group
SOP - standard operating procedure
< - Analyte not detected above associated reporting limit.
-- - No data reported

TABLE A 9-1
GROUNDWATER ELEVATIONS
Chemours Fayetteville Works, North Carolina

Area	Aquifer	Well ID	Gauging Date	Northing (ft, SPCS NAD83)	Easting (ft, SPCS NAD83)	Screened Interval (ft bgs)	TOC Elevation (ft NAVD 88)	Depth to Water (ft, from TOC)	Groundwater Elevation (ft NAVD88)
Onsite	Black Creek Aquifer	BCA-01	15-Oct-19	399,780.06	2,050,662.22	91 - 101	146.30	58.92	87.38

Notes:

1. Area - refers to location of well within site property boundary (“Onsite”) and outside property boundary (“Offsite”)
2. Aquifer - refers to primary aquifer unit well screen is estimated to be screened within
3. DRY - Water levels could not be calculated because well was dry.
4. NM - Not Measured. Water levels were not measured because well location was not accessible at the time of measurement due to well located within the "blast zone" or well was pumping (NAF-03, NAF-12 and M
5. -- - Groundwater elevation data not available because well was either dry, not accessible or was pumping at the time of measurement
6. NAF-05A and NAF-05B located in exclusion zone - Well location not safely accessible at the time of measurement.
7. Water levels were measured during a single synoptic event over a continuous 24-hour period.
8. Survey completed by Freeland-Clinkscales & Associates of NC.
9. Northing and Easting provided in North Carolina State Plane System (zone 3200), North American Datum 1983.
10. Vertical datum is North American Vertical Datum of 1988.

ft bgs - feet below ground surface
NAVD88 - North American Vertical Datum of 1988
TOC - Top of Casing
ft SPCS NAD83 - feet State Plane Coordinate System, North American Datum of 1983

Notes:
1. Well pairs only include locations where depth to water level in both wells were synoptically measured in October 2019.
2. Calculated negative vertical gradient values represent potential for upward flow and positive vertical gradient values represent potential for downward flows.
3. "s" and "d" represent shallower and deeper well screens between the wells in each pair.
4. Direction indicates potential for upward or downward groundwater flow in each well pair.
5. Water column depth from Old Outfall 002 channel bottom presented. Measurements collected during volumetric flow measurements presented in the *Seeps and Creeks Investigation Report* (Geosyntec, 2019).

NAD83 - North American Datum of 1983; horizontal control datum
NAVD88 - North American Vertical Datum of 1988; vertical control datum established in 1991
ft bgs - feet below ground surface
TOC - top of casing
-- data not available

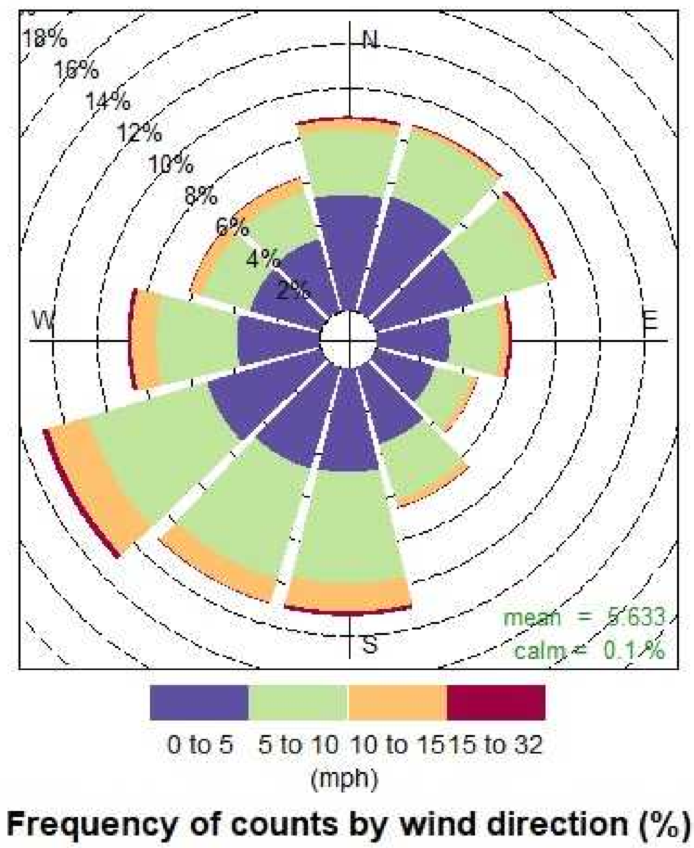
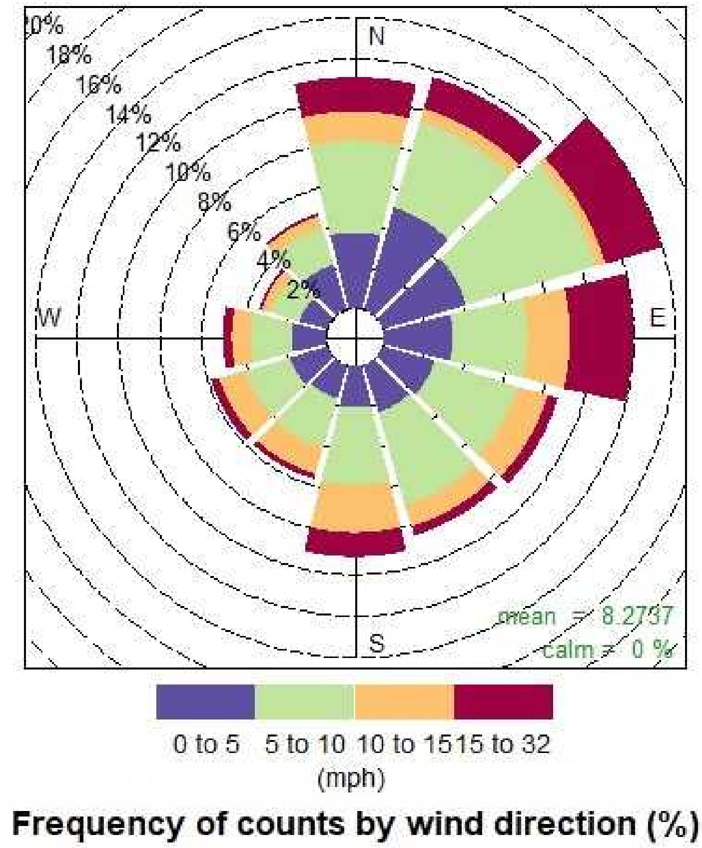
Wind Rose for Full Data Set



Wind Rose for Rain Events



Notes:

mph - miles per hour

1. Wind measurements collected at the Site for the period from 1 January 2018 to 15 May 2019.
2. Concentric circles indicate the relative proportion of winds from a given direction and speed.
3. Wedges represent the direction the winds are coming from.
4. Color indicates wind speed.
5. 575 total hours (5%) of rain and 10,738 total hours (95%) without rain at the Site for the period from1 January 2018 to 15 May 2019.

Historical Onsite Sources
- Air
- Water

Notes:
1. Historical air sources are manufacturing areas where PFAS were emitted to air. The Site by December 31, 2019 will be operating a Thermal Oxidizer that in combination with other control technologies reduces facility wide air emissions of PFAS by 99%.
2. Historical water sources are areas where process water was released to soil and groundwater. Site infrastructure upgrades and offsite disposal of process water has mitigated these sources.

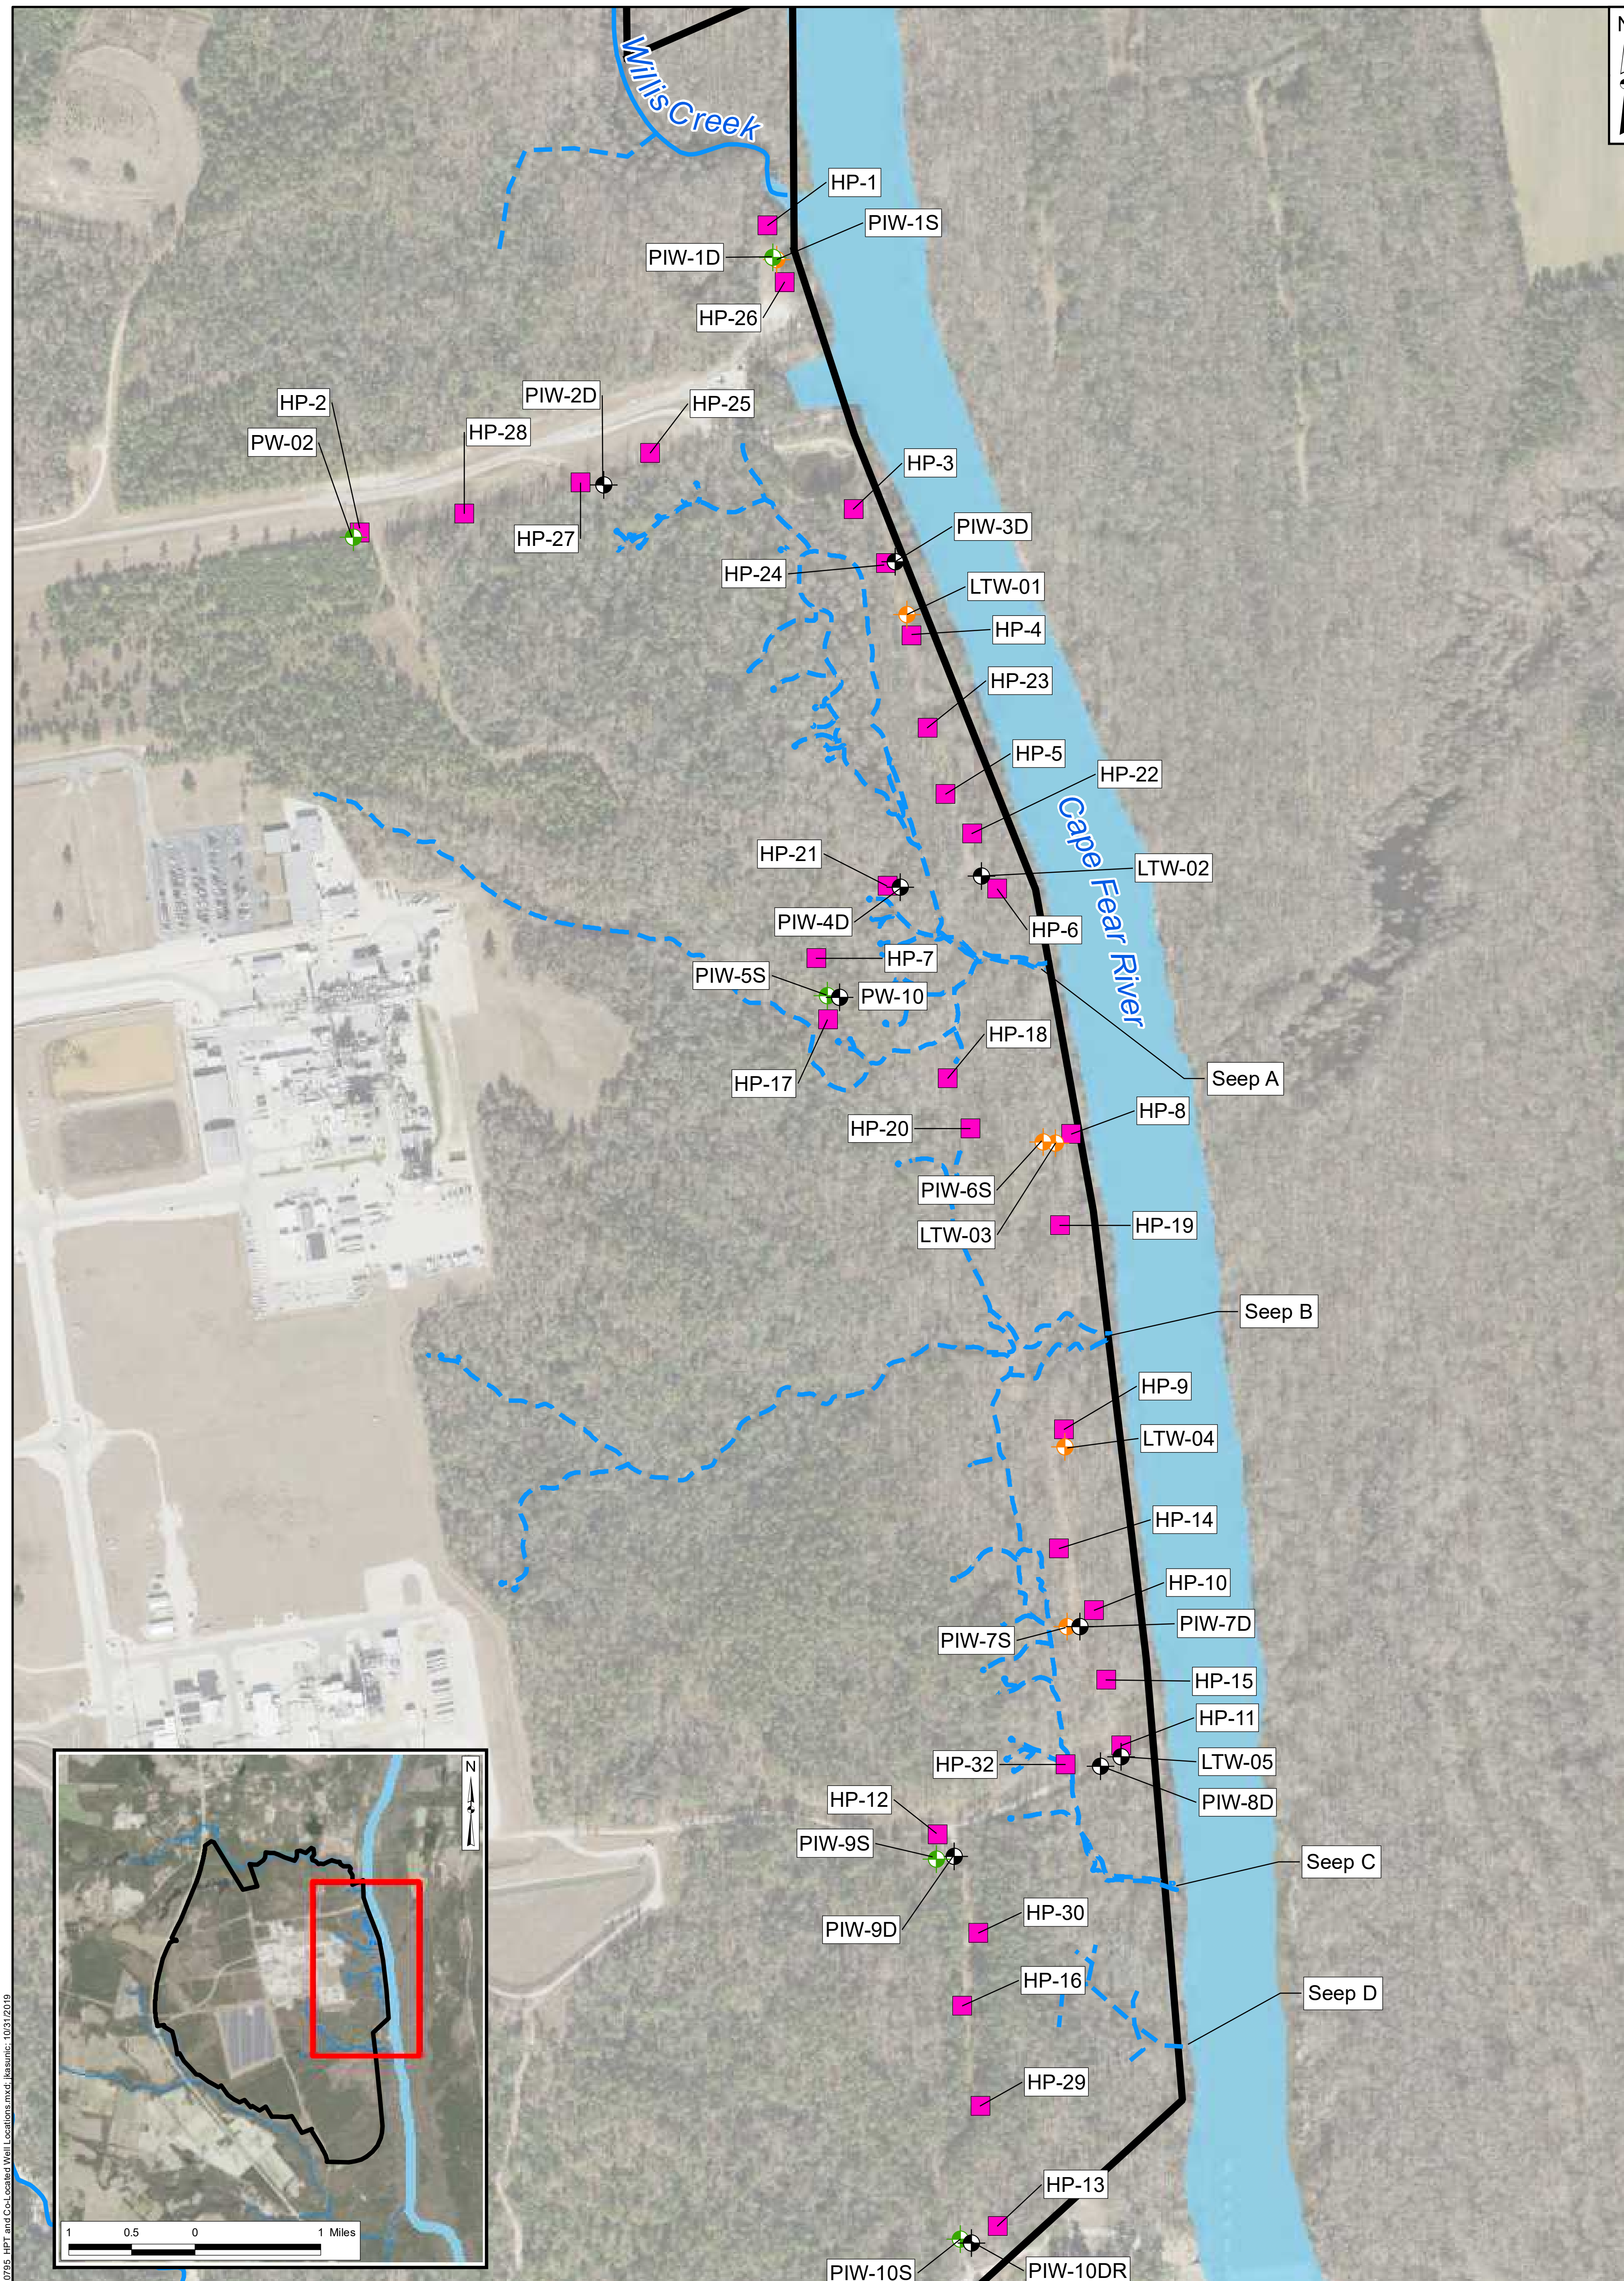
Figure A6-1

Projection: NAD 1983 StatePlane North Carolina FIPS 3200 Feet; Units in Foot US



Legend
Well Type

- Surficial Aquifer
- Floodplain Deposits
- Black Creek Aquifer
- HPT/EC Boring
- Observed Seep
- Nearby Tributary
- Site Boundary

Notes:
HPT - Hydraulic Profiling Tool
EC - Electrical Conductivity
1. Due to the scale of the map, pairs of wells that are in close proximity have been offset for visibility. Therefore, the placement of these wells on this map may not exactly reflect their true geographic coordinates.
2. HP- locations were not surveyed and considered approximate.
3. PIW and PW-well locations were sureyed by a licensed North Carolina Surveyor.
4. The outline of the River shown on this figure is approximate (River outline based on compilation of open data sources from ArcGIS online service and North Carolina Department of Environmental Quality Online GIS - Major Hydro shapefile).
5. Basemap source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community.

Notes

NGVD29 - National Geodetic Vertical Datum of 1929
NAVD88 – North American Vertical Datum of 1988
USGS - United States Geological Survey

1. Figure includes water level data from January 1, 2014 to September 10, 2019.
2. Water level data obtained for USGS gauges at Fayetteville (USGS 02104000), W.O.Huske (USGS 2105500) and Lock and Dam #1 (USGS 02105769) from National Water Information System (URL: https://waterdata.usgs.gov/nwis/inventory/?site_no=02105769, date accessed: 2019-09-24)
3. Measured water level datum converted from feet NGVD29 to feet NAVD88 using National Oceanic and Atmospheric Administration's VDatum tool available at vdatum.noaa.gov.
4. Line inside boxes represents the median water level.
5. Bottom and top of boxes represent the 25th and 75th percentile water levels, respectively.
6. Extent of whiskers represent range of observed water levels.

Legend

Well Type

- Black Creek Aquifer
- Surficial Aquifer
- Site Boundary

Notes:
All measurements are in ng/L (nanograms per litre).
< - Analyte not detected above associated reporting limit.
J - Analyte detected. Reported value may not be accurate or precise.
UJ - Analyte not detected. Reporting limit may not be accurate or precise.

1. Black lines represent cardinal directions (N, E, S, W)
2. Only the six most frequently detected Table 3+ compounds in offsite wells are shown.
3. Due to the scale of the map, pairs of wells that are in close proximity have been offset for visibility. Therefore, the placement of these wells on this map do not reflect their true geographic coordinates.
4. Date indicated is date of sample collection.
5. Table 3+ compounds abbreviations referenced in Table A2-1 of the report.
6. "DRY" indicates well was dry at the time of sampling.
7. Basemap sources: Esri, HERE, Garmin, Intermap, increment P Corp., GEBCO, USGS, FAO, NPS, NRCAN, GeoBase, IGN, Kadaster NL, Ordnance Survey, Esri Japan, METI, Esri China (Hong Kong), swisstopo, © OpenStreetMap contributors, and the GIS User Community

DATA REVIEW NARRATIVES AND LABORATORY REPORTS

DATA REVIEW NARRATIVES AND LABORATORY REPORTS

Data review narratives are included in this appendix. Due to file size limits, analytical laboratory reports will be provided separately with the hard copy of the report.

All analytical data were reviewed using the Data Verification Module (DVM) within the Locus™ Environmental Information Management (EIM) system, which is a commercial software program used to manage data. Following the DVM process, a manual review of the data was conducted. The DVM and the manual review results were combined in a data review narrative report for each set of sample results, which were consistent with Stage 2b of the EPA Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use (EPA-540-R-08-005 2009). The narrative report summarizes which samples were qualified (if any), the specific reasons for the qualification, and any potential bias in reported results. The data usability, in view of the project's data quality objectives (DQOs), was assessed and the data were entered into the EIM system.

The data were evaluated by the DVM against the following data usability checks:

- Hold time criteria;
- Field and laboratory blank contamination;
- Completeness of QA/QC samples;
- MS/MSD recoveries and the relative percent differences (RPDs) between these spikes;
- Laboratory control sample/control sample duplicate recoveries and the RPD between these spikes;
- Surrogate spike recoveries for organic analyses; and
- RPD between field duplicate sample pairs.

ADQM DATA REVIEW
NARRATIVE

Site	**Chemours FAY – Fayetteville**
Project	**GW Sampling 4Q19**
Project Reviewer	**Michael Aucoin, AECOM as a Chemours contractor**
Sampling Dates	**October 18, 22 – 25, and 28 – 31, 2019** **November 1, 4 – 8, 2019**

Analytical Protocol

Laboratory	Analytical Method	Parameter(s)
TestAmerica - Sacramento	Cl. Spec. Table 3 Compound SOP	Table 3+ compounds incl HFPO-DA

Sample Receipt

The following items are noted for this data set:

- All samples were received in satisfactory condition and within EPA temperature guidelines on:

  October 25, 29, and 31, 2019
  November 1, 8, and 12, 2019

Data Review

The electronic data submitted for this project was reviewed via the Data Verification Module (DVM) process.

Overall the data is acceptable for use without qualification, except as noted below:

- HFPO-DA results in some groundwater samples were qualified B and the reported results may be biased high, or false positives, due to a comparable concentration found in the associated equipment blank.
- Several analytical results have been qualified J as estimated, and non-detect results qualified UJ indicating an estimated reporting limit, due to a poor lab control or matrix spike recovery; and poor lab replicate precision. See the Data Verification Module (DVM) Narrative Report for which samples were qualified, the specific reasons for qualification, and potential bias in reported results.

Attachments

The DVM Narrative report is attached. The lab reports due to a large page count are stored on an AECOM network shared drive and are available to be posted on external shared drives, or on a flash drive.

Data Verification Module (DVM)

The DVM is an internal review process used by the ADQM group to assist with the determination of data usability. The electronic data deliverables received from the laboratory are loaded into the Locus EIM™ database and processed through a series of data quality checks, which are a combination of software (Locus EIM™ database Data Verification Module (DVM)) and manual reviewer evaluations. The data is evaluated against the following data usability checks:

- Field and laboratory blank contamination
- US EPA hold time criteria
- Missing Quality Control (QC) samples
- Matrix spike(MS)/matrix spike duplicate (MSD) recoveries and the relative percent differences (RPDs) between these spikes
- Laboratory control sample(LCS)/control sample duplicate (LCSD) recoveries and the RPD between these spikes
- Surrogate spike recoveries for organic analyses
- RPD between field duplicate sample pairs
- RPD between laboratory replicates for inorganic analyses
- Difference / percent difference between total and dissolved sample pairs.

There are two qualifier fields in EIM:

Lab Qualifier is the qualifier assigned by the lab and may not reflect the usability of the data. This qualifier may have many different meanings and can vary between labs and over time within the same lab. Please refer to the laboratory report for a description of the lab qualifiers. As they are lab descriptors they are not to be used when evaluating the data.

Validation Qualifier is the 3rd party formal validation qualifier if this was performed. Otherwise this field contains the qualifier resulting from the ADQM DVM review process. This qualifier assesses the usability of the data and may not equal the lab qualifier. The DVM applies the following data evaluation qualifiers to analysis results, as warranted:

Qualifier	**Definition**
B	Not detected substantially above the level reported in the laboratory or field blanks.
R	Unusable result. Analyte may or may not be present in the sample.
J	Analyte present. Reported value may not be accurate or precise.
UJ	Not detected. Reporting limit may not be accurate or precise.

The **Validation Status Code** field is set to “DVM” if the ADQM DVM process has been performed. If the DVM has not been run, the field will be blank.

If the DVM has been run (**Validation Status Code** equals “DVM”), use the **Validation Qualifier.**

DVM Narrative Report

Site: Fayetteville **Sampling Program:** GW Sampling 4Q19 **Validation Options:** LABSTATS

Validation Reason Contamination detected in equipment blank(s). Sample result does not differ significantly from the analyte concentration detected in the associated equipment blank(s).

APPENDIX B

SUPPORTING TABLES, FIGURES, FIELD RECORDS AND LABORATORY REPORTS

This document presents supporting documents that include the following:

- Figure B-1A: Sample and Flow Measurement Locations September 2019 Event;
- Figure B-1B: Cape Fear River Sample Locations September 2019 Event;
- Figure B-2: Total Table 3+ Concentrations – September 2019 Event;
- Figure B-3: HFPO-DA Concentrations – September 2019 Event;
- Figure B-4: Cape Fear River Total Table 3+ Concentrations September 2019 Event;
- Figure B-5: Cape Fear River HFPO-DA Concentrations September 2019 Event;
- Table B-1: Well Development Stabilized Field Parameters;
- Table B-2: Groundwater Sampling Stabilized Field Parameters;
- Table B-3: On and Offsite Resampled Groundwater Well Analytical Results – July to November 2019;
- Table B-4: September 2019 Mass Loading Model Location Summary;
- Table B-5: Analytical Methods and Analyte List;
- Table B-6: Analytical Results;
- Records of Well Development;
- Records of Well Sampling; and
- Attachment B: Data Validation Module.

Legend

- Flow Measurement Location
- Sample Location
- Observed Seep
- Nearby Tributary
- Site Boundary

Notes:

* - Flow measurement was taken at W.O. Huske Dam - USGS Gauge Site No. 02105500

1. Flow at Old Outfall 002, Seep A, Seep B and Seep C locations were measured using flumes.
2. Flow at Seep D was measured using salt diultion.
3. Flow at Willis Creek and Georgia Branch Creek were measured using flow velocity method.
4. Results of estimated flow at these locations are provided in Table 5 and Table 7 with supplemental flow measurement data included in Appendix B.
5. The outline of Cape Fear River is approximate and is based on open data from ArcGIS Online and North Carolina Department of Environmental Quality Online GIS.
6. Basemap sources: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community.

Notes:

1. Stabilized field parameters following well development completion reported here.
2. Well development forms included in Appendix B of this report.

Abbreviations:

DO - Dissolved Oxyg mS/cm - milli Siemens per centimeter

ORP - Oxidation Redu °C - degree celsius

Spec. Cond. - Specific Conductivity

Temp. - Temperature

mg/L - milligrams per liter

mV - millivolts

NTU - Nephelometric Turbidity Units

Notes:
1. PIW-1S and Bladen-1S were dry at the time of sampling
2. Duplicate samples collected at PIW-4D, Cumberland-1D and PW-15R
3. Stabilized field parameters following well purging reported here.
4. Well purging and groundwater sampling forms included in Appendix B of this report.

Abbreviations:
DO - Dissolved Oxygen
ORP - Oxidation Reduction Potential
Spec. Cond. - Specific Conductivity
Temp. - Temperature
mg/L - milligrams per liter
mV - millivolts
NTU - Nephelometric Turbidity Units

SEPTEMBER 2019 MASS LOADING MODEL LOCATION SUMMARY
Chemours Fayetteville Works, North Carolina

Location ID	Location Description	Sample Collection	Flow Measurement
		Sep-19	Sep-19
OLDOF-1	Old Outfall 002 Location 1	Y	--
OLDOF-2	Old Outfall 002 Location 2	--	Y
SEEP-A-1	Seep A Location 1	Y	Y
SEEP-A-3	Seep A Location 3	Y	Y
SEEP-A-4	Seep A Location 4	Y	Y
SEEP-A-TR1	Seep A Tributary 1	Y	Y
SEEP-B-1	Seep B Location 1	Y	Y
SEEP-B-2	Seep B Location 2	Y	Y
SEEP-B-TR1	Seep B Tributary 1	Y	Y
SEEP-B-TR2	Seep B Tributary 2	Y	Y
SEEP-C-1	Seep C Location 1	Y	Y
SEEP-D-1 (2)	Seep D Location 1	Y	Y
WC-1	Willis Creek Location 1	Y	Y
GBC-1	Georgia Branch Creek Location 1	Y	Y
CFR-MILE-52	Cape Fear River Mile 52	Y	--
CFR-MILE-56	Cape Fear River Mile 56	Y	--
CFR-MILE-68	Cape Fear River Mile 68	Y	--
CFR-MILE-76	Cape Fear River Mile 76	Y	--
CFR-BLADEN	Cape Fear River at Bladen Bluffs	Y	--
CFR-KINGS	Cape Fear River at Kings Bluff	Y	--
W.O. Huske Dam	USGS Gauge Site No. 02105500	--	Y
Excess River Water	Excess River Water	Y	Y
Outfall 002	Outfall 002 location	Y	Y

Notes:

1. Flow at Old Outfall 002, Seep A, Seep B and Seep C locations were measured using flumes.
2. Flow at Seep D was measured using salt diultion.
3. Flow at Willis Creek and Georgia Branch Creek were measured using flow velocity method.
4. Results of estimated flow at these locations are provided in Table 6 and supplemental flow measurement data is included in Attachment C.

Y - Sampling or flow measurement was conducted

Notes:
1. **Bold** - Analyte detected above associated reporting limit
2. F53B-Major, F53B-Minor, DONA, ADONA and NaDONA were not reported by the laboratory at the time of this analysis.

Abbreviations:
B - analyte detected in an associated blank
J - Analyte detected. Reported value may not be accurate or precise
ng/L - nanograms per liter
QA/QC - Quality assurance/ quality control
SOP - standard operating procedure
UJ – Analyte not detected. Reporting limit may not be accurate or precise.
< - Analyte not detected above associated reporting limit.

DATA REVIEW NARRATIVES AND LABORATORY REPORTS

DATA REVIEW NARRATIVES AND LABORATORY REPORTS

Data review narratives are included in this appendix. Due to file size limits, analytical laboratory reports will be provided separately with the hard copy of the report.

All analytical data were reviewed using the Data Verification Module (DVM) within the Locus^{TM} Environmental Information Management (EIM) system, which is a commercial software program used to manage data. Following the DVM process, a manual review of the data was conducted. The DVM and the manual review results were combined in a data review narrative report for each set of sample results, which were consistent with Stage 2b of the EPA Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use (EPA-540-R-08-005 2009). The narrative report summarizes which samples were qualified (if any), the specific reasons for the qualification, and any potential bias in reported results. The data usability, in view of the project's data quality objectives (DQOs), was assessed and the data were entered into the EIM system.

The data were evaluated by the DVM against the following data usability checks:

- Hold time criteria;
- Field and laboratory blank contamination;
- Completeness of QA/QC samples;
- MS/MSD recoveries and the relative percent differences (RPDs) between these spikes;
- Laboratory control sample/control sample duplicate recoveries and the RPD between these spikes;
- Surrogate spike recoveries for organic analyses; and
- RPD between field duplicate sample pairs.

ADQM DATA REVIEW
NARRATIVE

Site Chemours FAY – Fayetteville

Project Creeks Seeps Old Outfall 002 9/19

Project Reviewer Michael Aucoin, AECOM as a Chemours contractor

Sampling Dates September 17 - 18, 2019

Analytical Protocol

Laboratory	Analytical Method	Parameter(s)
TestAmerica - Sacramento	537 Modified	PFAS[1]
TestAmerica - Sacramento	Cl. Spec. Table 3 Compound SOP	Table 3+ compounds

[1] Perfluoroalkylsubstances, a list of 33 compounds including HFPO-DA.

Sample Receipt

The following items are noted for this data set:

All samples were received in satisfactory condition and within EPA temperature guidelines on September 19, 2019

Data Review

The electronic data submitted for this project was reviewed via the Data Verification Module (DVM) process.

Overall the data is acceptable for use without qualification, except as noted below:

- Some table 3+ results in three water samples were qualified B and the reported results may be biased high, or false positives, due to a comparable concentration found in the associated equipment blank. Byproduct 5 and PFMOAA results in sample ID EXCESS RIVER WATER-091719 were also impacted by an MS RPR outside criteria indicating estimated results but the B qualifier supercedes the J qualifier.
- Several analytical results have been qualified J as estimated, and non-detect results qualified UJ indicating an estimated reporting limit, due to a poor laboratory matrix spike; sample analysis which exceeded the laboratory preparation hold time; and poor field duplicate or lab replicate precision. See the Data Verification Module (DVM) Narrative Report for which samples were qualified, the specific reasons for qualification, and potential bias in reported results.

Attachments

The DVM Narrative report is attached. The lab reports due to a large page count are stored on an AECOM network shared drive and are available to be posted on external shared drives, or on a flash drive.

Data Verification Module (DVM)

The DVM is an internal review process used by the ADQM group to assist with the determination of data usability. The electronic data deliverables received from the laboratory are loaded into the Locus EIM™ database and processed through a series of data quality checks, which are a combination of software (Locus EIM™ database Data Verification Module (DVM)) and manual reviewer evaluations. The data is evaluated against the following data usability checks:

- Field and laboratory blank contamination
- US EPA hold time criteria
- Missing Quality Control (QC) samples
- Matrix spike(MS)/matrix spike duplicate (MSD) recoveries and the relative percent differences (RPDs) between these spikes
- Laboratory control sample(LCS)/control sample duplicate (LCSD) recoveries and the RPD between these spikes
- Surrogate spike recoveries for organic analyses
- RPD between field duplicate sample pairs
- RPD between laboratory replicates for inorganic analyses
- Difference / percent difference between total and dissolved sample pairs.

There are two qualifier fields in EIM:

Lab Qualifier is the qualifier assigned by the lab and may not reflect the usability of the data. This qualifier may have many different meanings and can vary between labs and over time within the same lab. Please refer to the laboratory report for a description of the lab qualifiers. As they are lab descriptors they are not to be used when evaluating the data.

Validation Qualifier is the 3rd party formal validation qualifier if this was performed. Otherwise this field contains the qualifier resulting from the ADQM DVM review process. This qualifier assesses the usability of the data and may not equal the lab qualifier. The DVM applies the following data evaluation qualifiers to analysis results, as warranted:

Qualifier	**Definition**
B	Not detected substantially above the level reported in the laboratory or field blanks.
R	Unusable result. Analyte may or may not be present in the sample.
J	Analyte present. Reported value may not be accurate or precise.
UJ	Not detected. Reporting limit may not be accurate or precise.

The **Validation Status Code** field is set to "DVM" if the ADQM DVM process has been performed. If the DVM has not been run, the field will be blank.

If the DVM has been run (**Validation Status Code** equals "DVM"), use the **Validation Qualifier.**

DVM Narrative Report

Site: Fayetteville **Sampling Program:** Creeks Seeps Old Outfall 002 9/19 **Validation Options:** LABSTATS

Validation Reason Contamination detected in equipment blank(s). Sample result does not differ significantly from the analyte concentration detected in the associated equipment blank(s).

APPENDIX C

K_{OW}, K_{OC} and Mass Distribution Calculations

APPENDIX C

MEASURED K_{OW} AND CALCULATED K_{OC} FOR TABLE 3+ COMPOUNDS

Laboratory studies were performed at Chemours Experimental Station in Wilmington, Delaware to determine Table 3+ PFAS octanol-water partition coefficients (K_{ow}) using liquid chromatography elution times (OECD, 2014). In this method, Table 3+ PFAS partition between the mobile solvent phase and the hydrocarbon stationary phase as they are transported along the column by the mobile phase. Compounds elute in proportion to their hydrocarbon-water partition coefficient, with hydrophilic chemicals eluted earlier and lipophilic chemicals later. K_{ow} is then estimated by determining the retention time for each compound in relation to reference compounds with known K_{ow} values.

K_{ow} tests were conducted on an Agilent 1290 Infinity II HPLC with an Agilent 6470 triple quad with an AJS-ESI source as the detector in multiple reaction monitoring mode (MS/MS filtering). The analytical column was a Phenomenex Gemini reversed phase C18 column 100 x 3 mm, 3 um particle size with 110 A pore size and TMS endcapping. The column was maintained at 50° C +/- 0.1° C by the LC column compartment oven. Mobile phase flow was isocratic at 0.5 mL/min. Table 3+ were separated into 4 groups to facilitate separation under isocratic conditions:

- Group 1 - MMF, DFSA, MTP, Byproduct 4, Byproduct 5, and R-EVE;
- Group 2 - PPF Acid and PMPA;
- Group 3 - PFMOAA, NVHOS, PFO2HxA, PEPA, PES, PFECA B, and PFO3A; and
- Group 4 - By product 6, Hydro Eve, By product 2, PFECA G, PFO4DA, Byproduct 1, Eve Acid, and PFO5DoA.

Mobile phases were prepared daily. Tests were conducted with different isocratic mobile phases methanol/water compositions for each group, and at two pH values (pH 5 [4.89 - 5.10] and pH 8 [8.10 – 8.29]) to span Site pH conditions. Mobile phases were buffered with 20 mM ammonium salt buffer (acetate for pH 5 and bicarbonate for pH 8). Analytes were prepared in a minimum of 90% mobile phase.

The retention time is described by the capacity factor k:

$$k = \frac{t_R - t_0}{t_R}$$

where t_R is the retention time of the Table 3+ compound, and t_0 is the average time a solvent molecule needs to pass through the column (the dead-time). K_{ow} values for Table 3+

compounds were estimated by experimentally determining k and then calculating K_{ow} using the following equation:

$$log\ K_{ow} = a + b\ x \log k$$

where a, b = linear regression coefficients were calculated with a linear regression curve of log K_{ow} and k of 11 reference PFAS compounds of varying structures (Table C-1 and Figure C-1). For DFSA, MTP, PPF, and PFMOAA, t_R was found to be less than t_0, thus log K_{ow} was estimated by extrapolation and extrapolated values are provided in parenthesis.

A linear regression curve between log K_{ow} and log K_{oc} was then developed using 20 reference compounds with known log K_{ow} and log K_{oc} (Table C-2 and Figure C-2). Results of the log K_{ow} and log K_{oc} values for Table 3+ PFAS are provided in Table 3 of the main CAP text.

Table C-1:Reference Compounds for Log Kow versus Retention Time Linear Regression Curve

Acronym	Name	Formula	CAS #	Log K_{ow}[1]

Compounds in parentheses were excluded from linear regression curve due to values not being compatible with PFAS structure correlations

MASS DISTRIBUTION CALCULATIONS FOR TABLE 3+ COMPOUNDS

The total mass of PFAS in saturated aquifers was calculated by summing PFAS in groundwater and PFAS sorbed on soils. The PFAS sorbed on saturated soil was calculated by taking the groundwater concentrations from a groundwater sample for each PFAS to PFAS sorbed on 0.1 kg soil using median fraction organic carbon f_{oc} similar lithologic units and K_{oc} values. For locations where f_{oc} wasn't measured, a median f_{oc} value from all lithologic units was used.

An analysis was performed to determine whether PFAS mass on and offsite was primarily associated with the unsaturated zone or the saturated zone. This analysis was conducted to help evaluate the potential relative benefit between corrective action for soils versus groundwater. The analysis was conducted by comparing the unsaturated zone total mass (mass in pore water and soil) to the saturated zone total mass (mass in groundwater and soil) for samples taken from the same location. Total mass was calculated for one cubic meter of material (unsaturated or saturated).

The total Table 3+ PFAS mass in the unsaturated zone was estimated by summing the total Table 3+ PFAS mass measured in soil samples from the unsaturated zone (this is assumed to include both PFAS n the pore water and PFAS sorbed on the soil).

The total Table 3+ PFAS mass in the saturated zone was calculated using groundwater data from samples representative of the saturated zone to estimate the total mass of PFAS in the soil from which the groundwater sample originated. Parameters used for the calculations were:

- Measured fraction organic carbon (f_{oc}) - values used for f_{oc} were the median value for the lithological unit from which the groundwater sample was collected. F_{oc} data are presented in the On and Offsite Assessment report (Geosyntec, 2019);
- Calculated K_{oc} values - provided earlier in this Appendix;
- Dry bulk density of the subsurface material -1.602 kg/L was used for all lithological units;
- Porosity – 40% was used for all lithological units.

The total mass of PFAS in groundwater and the total mass of PFAS in the soil were then added together to calculate a total mass of PFAS in the saturated zone. For this exercise, non-detects were not included in any calculations.

Results are provided in Table C-3. Results are shown in Figure 4 in the main CAP text.

Memorandum

Date: December 31, 2019

To: The Chemours Company FC, LLC

From: Geosyntec Consultants of NC, PC

Subject: Southwestern Offsite Seeps Assessment

INTRODUCTION AND OBJECTIVES

Geosyntec Consultants of NC, PC (Geosyntec) has prepared this memorandum for The Chemours Company FC, LLC (Chemours) for the Fayetteville Works facility in Bladen County, North Carolina (the Site). The purpose of this memorandum is to describe the findings of the Southwestern Offsite Seeps Assessment. Groundwater seeps are a common hydrogeological feature in areas of sloping terrain. Onsite four groundwater seeps (Seeps A, B, C and D; Figure 1) were identified in early 2019 (Geosyntec, 2019a). These onsite seeps informed the overall conceptualization of per- and polyfluoroalkyl substances (PFAS) mass transport from the Site to the Cape Fear River. The assessment described in this memorandum was undertaken to identify and sample the groundwater seeps located between the Old Outfall 002 and Georgia Branch Creek to assess Table 3+ PFAS concentrations and Table 3+ PFAS signatures (i.e. aerial vs. process water signatures).

METHODS

The southwestern offsite seeps were identified by observation from a boat along the west shore of the Cape Fear River from the Old Outfall 002 to Georgia Branch Creek (Appendix A). The shoreline was observed for any surface water runoff, ground water seeps or erosional features indicative of flowing water. A total of ten seeps were identified on the western shore of the Cape Fear River (Figure 1) along with one erosional feature which contained no flow of water. Nine of the ten seep (E to M) were sampled. Chemours obtained verbal agreement for sampling the seeps to the exception of the Lock and Dam Seep; Chemours is presently working towards obtaining a written access agreement to sample the Lock and Dam Seep which is immediately adjacent a boat launch ramp.

Once a seep was identified, it was sampled by submerging a 250 mL HDPE sampling bottle to capture the water flowing from the seep, facing into the direction of flow. Two bottles were collected for each location and were composited together at the laboratory. Seeps E, F, J and L did not have enough flow to enable sampling by placing bottle in the flow of water; the seeps only had drops of water seeping from bank. Instead, these seeps (Seeps E, F, J and L) were sampled by collecting the trickle of water from a freshly cut section of the embankment. For Seep J, one bottle was collected from the seep and another from the wetland area upstream that is believed to feed the ground water of Seep J. While no above ground flow was observed between Seep J and the wetland area there was a continuous area of wetland vegetation connecting the seep and the wetland suggesting a hydrological connection. For Seep E and Seep F water was collected from an upstream pool of water along the seep channel rather than directly at the mouth. The highest flow was observed at Seep K which had clearly visible surface water flowing while low trickling flow was observed at Seeps G, H, I and M (Appendix B).

Seep samples were analyzed by the following methods:

- EPA Method 537 Mod (includes Hexafluoropropylene oxide dimer acid [HFPO-DA]) at TestAmerica Sacramento; and
- Table 3+ Standard Operating Protocol (SOP) at TestAmerica Sacramento

Seep PFAS signatures were assessed using hierarchical cluster analysis as described in the Corrective Action Plan (Geosyntec, 2019a).

DATA QUALITY

Analytical data were reviewed using the Data Verification Module (DVM) within the Locus™ Environmental Information Management (EIM) system, which is a commercial software program used to manage data. Following the DVM process, a manual review of the data was conducted. The DVM and manual review results were combined in a data review narrative report for each set of sample results, which were consistent with Stage 2b of the EPA Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use (EPA-540-R-08-005 2009). The narrative report summarizes which samples were qualified (if any), the specific reasons for the qualification, and any potential bias in reported results. The data usability, in view of the project's data quality objectives (DQOs), was assessed and the data were entered into the EIM system. The data were evaluated by the DVM against the following data usability checks:

- Hold time criteria;
- Field and laboratory blank contamination;
- Completeness of QA/QC samples;
- MS/MSD recoveries and the relative percent differences (RPDs) between these spikes;

- Laboratory control sample/control sample duplicate recoveries and the RPD between these spikes;
- Surrogate spike recoveries for organic analyses; and
- RPD between field duplicate sample pairs.

The analytical results for the offsite seeps are presented in Table 1. Results are presented with all validation flags. The "J" and "UJ" flagged results indicate usable data, which should be considered as quantitatively estimated. The results are not necessarily within the laboratory's criteria for accuracy and precision of the test method employed, but in the reviewer's professional judgment are usable. Laboratory reports and data review narratives are provided in Appendix C. One field blank sample was analyzed for Table 3+ and Mod 537 PFAS compounds. All analytes were non-detect indicating there was no cross-contamination in the field blank.

RESULTS AND DISCUSSION

Total Table 3+ PFAS concentrations at the offsite seeps ranged from 2,600 ng/L at Seep J to 6,800 ng/L at Seep F (Table 1). The highest single compound measured was PMPA at Seep J with a concentration of 2,800 ng/L. The seeps with the highest concentration of total Table 3+ (Seep E and Seep G; 6,200 and 6,800 ng/L respectively) are located on the northern part of the study area, about 500 feet south of Old Outfall 002 (Figure 2). The other seeps have lower total Table 3+ concentration with the lowest (Seep J; 2,600 ng/L) is located in the middle of the study area, half a mile south of Old Outfall 002. The data gathered here shows an overall decreasing trend in total Table 3+ PFAS concentration while moving southward towards Georgia Branch Creek. The sample collected from Georgia Branch Creek in September 2019 (Geosyntec, 2019b) had a total Table 3+ concentration of 2,100 ng/L, similar to the concentrations found at Seep H through M. Compared to the onsite seeps and Old Outfall 002 the offsite seeps have lower concentrations of Total Table 3+ PFAS by one to two orders of magnitude (Figure 2).

Similar to Georgia Branch Creek, all of the offsite seeps exhibited an aerial PFAS signature (Figure 3). These results indicate that the PFAS in these offsite seeps likely originated from aerial PFAS deposition. The PFAS then subsequently infiltrated to groundwater and eventually discharged from these seeps to the Cape Fear River.

APPENDIX C
DATA REVIEW NARRATIVES AND LABORATORY REPORTS

Data review narratives are included in this attachment. Due to file size limits, analytical laboratory reports will be provided separately with the hard copy of the report.

ADQM DATA REVIEW
NARRATIVE

Site **Chemours FAY – Fayetteville**

Project **2019 OFFSITE SEEP SAMPLING**

Project Reviewer **Michael Aucoin, AECOM as a Chemours contractor**

Sampling Dates **October 21 - 22, 2019**

Analytical Protocol

Laboratory	Analytical Method	Parameter(s)
TestAmerica - Sacramento	537 Modified	PFAS[1]
TestAmerica - Sacramento	Cl. Spec. Table 3 Compound SOP	Table 3+ compounds

[1] Perfluoroalkylsubstances, a list of 37 compounds including HFPO-DA.

Sample Receipt

The following items are noted for this data set:

All samples were received in satisfactory condition and within EPA temperature guidelines on October 23, 2019

Data Review

The electronic data submitted for this project was reviewed via the Data Verification Module (DVM) process.

Overall the data is acceptable for use without qualification, except as noted below:

- Some analytical results have been qualified J as estimated, and non-detect results qualified UJ indicating an estimated reporting limit, due to a poor surrogate or laboratory matrix spike recovery and poor lab replicate precision. See the Data Verification Module (DVM) Narrative Report for which samples were qualified, the specific reasons for qualification, and potential bias in reported results.

Attachments

The DVM Narrative report is attached. The lab reports due to a large page count are stored on an AECOM network shared drive and are available to be posted on external shared drives, or on a flash drive.

Data Verification Module (DVM)

The DVM is an internal review process used by the ADQM group to assist with the determination of data usability. The electronic data deliverables received from the laboratory are loaded into the Locus EIM™ database and processed through a series of data quality checks, which are a combination of software (Locus EIM™ database Data Verification Module (DVM)) and manual reviewer evaluations. The data is evaluated against the following data usability checks:

- Field and laboratory blank contamination
- US EPA hold time criteria
- Missing Quality Control (QC) samples
- Matrix spike(MS)/matrix spike duplicate (MSD) recoveries and the relative percent differences (RPDs) between these spikes
- Laboratory control sample(LCS)/control sample duplicate (LCSD) recoveries and the RPD between these spikes
- Surrogate spike recoveries for organic analyses
- RPD between field duplicate sample pairs
- RPD between laboratory replicates for inorganic analyses
- Difference / percent difference between total and dissolved sample pairs.

There are two qualifier fields in EIM:

Lab Qualifier is the qualifier assigned by the lab and may not reflect the usability of the data. This qualifier may have many different meanings and can vary between labs and over time within the same lab. Please refer to the laboratory report for a description of the lab qualifiers. As they are lab descriptors they are not to be used when evaluating the data.

Validation Qualifier is the 3rd party formal validation qualifier if this was performed. Otherwise this field contains the qualifier resulting from the ADQM DVM review process. This qualifier assesses the usability of the data and may not equal the lab qualifier. The DVM applies the following data evaluation qualifiers to analysis results, as warranted:

Qualifier	**Definition**
B	Not detected substantially above the level reported in the laboratory or field blanks.
R	Unusable result. Analyte may or may not be present in the sample.
J	Analyte present. Reported value may not be accurate or precise.
UJ	Not detected. Reporting limit may not be accurate or precise.

The **Validation Status Code** field is set to "DVM" if the ADQM DVM process has been performed. If the DVM has not been run, the field will be blank.

If the DVM has been run (**Validation Status Code** equals "DVM"), use the **Validation Qualifier.**

APPENDIX E
PFAS Signatures Assessment

APPENDIX E: PFAS SIGNATURE METHODS AND RESULTS

1. INTRODUCTION AND OBJECTIVES

This appendix provides details on the statistical method used to facilitate identification of PFAS signatures in the onsite and offsite areas and a summary of the results of the analysis (Table E-1).

Hierarchical cluster analysis (HCA), was used to evaluate the relative proportions of Table 3+ PFAS concentrations in onsite and offsite groundwater and surface water to identify: (i) groups of samples that share similar concentration compositions and (ii) the Total Table 3+ PFAS compounds driving these groupings. The results of the HCA were used to infer PFAS signatures across the onsite and offsite areas and to provide a line of evidence regarding different PFAS pathways. The analysis was performed using R software (R Core Team, 2018).

2. HIERARCHICAL CLUSTER ANALYSIS

The hierarchical cluster analysis was performed similarly to the one performed for the On and Offsite Assessment (Geosytnec, 2019); however, the data set was expanded to include onsite and offsite groundwater samples collected from the following locations:

- Onsite and offsite groundwater wells;
- Offsite private drinking water wells;
- Cape Fear River, Willis Creek, Georgia Branch Creek, and Old Outfall 002; and
- Onsite and offsite groundwater seeps.

Also, this analysis used data for the 11 Table 3+ PFAS data on Attachment C of the Consent Order. Private well data were analyzed for only the Attachment C PFAS and, therefore, this was the set of Table 3+ PFAS that could facilitate the identification and subsequent comparison of signatures between the samples of private well data and other data sets.

Hierarchical cluster analysis (HCA) is a multivariate statistical method that can identify common groups, i.e., clusters, of wells within a large data set based on their PFAS concentration compositions. HCA builds a hierarchy from the bottom-up and does not require the number of clusters to be specified beforehand (Hastie et al. 2009).

The idea behind the HCA clustering algorithm is as follows:

1. Begin by assuming each groundwater well is in its own cluster.
2. Identify the closest two clusters and combine them into one cluster.
3. Repeat the above step until all the data points are in a single cluster.

To perform step 2 above, a distance metric (to quantify the dissimilarity between clusters) and an agglomeration criterion need to be selected. Many distances are available (Manhattan, Euclidean, etc.) as well as several agglomeration methods (Ward, single, centroid, etc.). For this analysis, the

Manhattan distance and Ward's method were used to perform the HCA. The Ward's method minimizes the sum of squares of any two (hypothetical) clusters that can be formed at each step. This method produces compact clusters of similar size and is one of the most common methods used for environmental concentration data.

The results of HCA are displayed using a tree-based graphical representation known as a dendrogram. Each leaf of the dendrogram (vertical line) corresponds to a well and wells that are similar to each other are merged into branches (horizontal lines). The height of each merge indicates the similarity between two clusters. Therefore, merges with higher heights represent less similar clusters.

To determine the optimal number of clusters, a "majority rule" approach can be used. This approach involves simultaneously calculating several indices (e.g., Elbow, Silhouette Gap statistics, etc.) to determine the relevant number of clusters and the number proposed by the majority of indices is the optimal number of clusters (Charrad et al., 2014).

3. RESULTS

The HCA identified four clusters of wells with differing Table 3+ PFAS compositions. The PFAS compositions across wells within a cluster were used to infer the following four PFAS signatures:

- Aerial deposition PFAS signature characterized by a mixture of PFAS compounds;
- Aerial deposition PFAS signature characterized by a predominant proportion of PMPA or HFPO-DA; and
- Combined process water PFAS signature characterized with a predominant proportion of PFMOAA.

For each proposed PFAS signature, the concentration compositions for all locations are shown in Table E-1. The spatial distribution of these proposed PFAS signatures are provided in Figures 2 in the main report.

EXECUTIVE SUMMARY

Geosyntec has prepared this *Offsite Human Health Screening Level Exposure Assessment* (SLEA) on behalf of The Chemours Company FC, LLC (Chemours) in support of developing a *Corrective Action Plan* (CAP) for the Chemours Fayetteville Works Facility in Bladen County, North Carolina (the Facility).

The overall goal of the SLEA is to refine understanding of the Facility Conceptual Site Model (CSM) in support of developing the CAP, which is accomplished by quantifying potential human intake and noncarcinogenic human health hazard from assumed exposure to Table 3+ per- and polyfluoroalkyl substances (PFAS) in the vicinity of the Facility. Table 3+ PFAS are the PFAS originating from air emissions and past process water releases at the Facility. The SLEA quantifies potential human exposure to the following media:

- offsite soil, drinking well water, and homegrown produce within a 10-kilometer radius of the Facility (subdivided into 12 exposure units);
- offsite surface water and fish tissue in the Cape Fear River, extending 10 miles upstream and 55 miles downstream of the Facility (subdivided into five [5] exposure units);
- surface water and fish tissue from an onsite Facility pond; and
- surface water from a private offsite pond.

Central tendency and upper-bound exposure point concentrations (EPCs) for soil, well water, surface water and fish fillets were calculated using empirical data whereas EPCs for produce were calculated using approved United States Environmental Protection Agency (USEPA) models. Exposure to soil, well water, and produce was evaluated for adult and child resident, farmer, and gardener populations. Exposure to surface water and fish tissue was evaluated for adult and child recreationalist populations. Potential PFAS intake from each medium was estimated using standard regulatory risk assessment equations that combine media-specific EPCs with conservative, receptor-specific exposure assumptions recommended by USEPA. Total hexafluoropropylene oxide dimer acid (HFPO-DA) intake calculated for each receptor-exposure scenario was compared to the North Carolina Department of Health and Human Services (NC DHHS) 2017 draft oral reference dose (RfDo) to yield a provisional noncarcinogenic human health hazard estimate.

Calculated hazards for HFPO-DA for all receptor-exposure scenarios evaluated in the SLEA are less than 1 which, as defined by USEPA, indicates adverse effects to human receptors are unlikely, including sensitive subpopulations. Untreated well water was identified as the primary source of potential PFAS intake and hazard. Additionally, when the SLEA accounts for the effectiveness of the Chemours-provided drinking water treatment systems that are currently in-place, PFAS intake via well water consumption and associated hazards are substantially reduced and may be as low as zero. While other media were not identified as significantly contributing to overall intake and hazard, human exposure to PFAS in environment media will continue to decrease over time as a result of Facility air emissions reductions.

1 INTRODUCTION

Geosyntec Consultants of NC, PC (Geosyntec) has prepared this Offsite Human Health Screening Level Exposure Assessment (SLEA) of Table 3+ (per- and polyfluoroalkyl substances) PFAS on behalf of The Chemours Company FC, LLC (Chemours) for the Fayetteville Works facility in Bladen County, North Carolina (Facility)[1]. Table 3+ PFAS, listed in Table 1, have been historically released from process water and air emissions at the Facility; however, Chemours' process water is currently sent for offsite disposal and air abatement controls being installed are reducing air emissions by 99 percent (%).

The purpose of the SLEA is to estimate potential offsite[2] human exposures to current conditions, influenced by historically-released or deposited Table 3+ PFAS and in consideration of control technologies being implemented. SLEA exposure estimates are calculated using regional[3] concentrations in environmental media in the vicinity of the Facility. The SLEA focuses on hexafluoropropylene oxide dimer acid (HFPO-DA[4]) while also estimating human exposures to 19 other PFAS presently capable of being analyzed using the Table 3+ standard operating protocol (SOP) method. The SLEA also presents the results of a provisional human health hazard characterization for HFPO-DA based on intakes quantified herein and the North Carolina Department of Health and Human Services (NC DHHS) 2017 draft oral reference dose (RfDo).

The content and findings of the SLEA should be reviewed in consideration of the following:

- The SLEA drinking water intake and provisional hazard estimates for residences in the vicinity of the Facility are initially calculated based on untreated well water which, in many cases, is not representative of drinking water conditions. Concentrations detected in groundwater are almost entirely the legacy of prior operations, mostly by Chemours' predecessor, and abatement and remediation measures already taken by Chemours have addressed and essentially abated releases of PFAS from Chemours' continuing operations at the Facility. As part of the Consent Order implementation, Chemours is required to offer replacement drinking water (in the form of public water or whole building filtration systems)

---

[1] An Ecological SLEA prepared by Geosyntec is being concurrently submitted with this document.
[2] Herein, "onsite" and "offsite" are used to distinguish areas within and outside of the Facility boundaries, respectively, as shown in Figure 1.
[3] PFAS concentrations and exposures are characterized herein as "regional" on the basis that they do not represent conditions at a specific point of exposure (e.g., pertinent to an individual or discrete residence or from a specific drinking water well). Rather, the SLEA assesses potential intake on the basis of Exposure Units (EUs) arrayed around and radiating from the approximately center-point of the Facility, as well as conditions in the Cape Fear River, proximal to the Facility.
[4] HFPO-DA is also referred to as GenX.

when private wells have HFPO-DA detected above 140 nanograms per liter (ng/L). For private drinking water wells, when any individual PFAS listed in Consent Order Attachment C, exceeds 10 ng/L or when total PFAS listed in Consent Order Attachment C exceed 70 ng/L, Chemours is required to offer residents or other persons up to three under-the-sink reverse osmosis drinking water systems. Chemours is required to offer temporary replacement water supplies (i.e., bottled water) to those properties qualifying for a filtration or reverse osmosis system until these systems have been provided. As noted above, the SLEA presents the results of a provisional hazard characterization, limited to HFPO-DA. Under Reasonable Maximum Exposure (RME) conditions, even in the absence of treatment, no receptor-specific, cumulative hazards exceed unity (1). The majority of hazard is associated with consumption of untreated drinking water; however, this exercise may be considered hypothetical, as qualifying residents or other persons (as described above) within the Facility zone of influence are provided with alternate or treated water supplies. All post-treatment drinking well water results are non-detect for all Table 3+ PFAS compounds, resulting in (essentially) zero drinking water-associated hazards. Intake and hazard estimates based on assumed HFPO-DA concentrations of 10 ng/L (the maximum concentration not qualifying for treatment) are up to two orders of magnitude lower than those calculated based on untreated well water reducing hazard estimates from being consistently less than 1 to consistently less than 0.1.

- Chemours is acting to reduce air emissions of PFAS from the Facility, including installation of a thermal oxidizer that will dramatically reduce aerial PFAS emissions from the Site, with reduction of aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, and expected comparable reductions for other PFAS. This is relevant since Table 3+ PFAS in offsite media originate from aerial deposition stemming from Facility emissions to air, which are described in the *On and Offsite Assessment Report* (Geosyntec, 2019c). Based on this, the present concentrations of offsite PFAS are expected to diminish over time through natural attenuation. Current conditions therefore, represent the highest expected concentrations in receiving media with future exposure diminishing over time. With a reduction in air emissions, associated soil and groundwater concentrations will attenuate over time, as will contributions to other receiving media, such as surface water and recreational fish species. Additionally, Chemours' process water is being sent for offsite disposal, eliminating a pathway that historically contributed PFAS to the river.

- The SLEA sampling, analyses, and evaluation methods were developed to provide screening-level estimates of intake and potential human health hazard to offsite populations. Like any regulatory risk assessment, the hazard estimates are not predictive of any health outcome. Rather, the findings are intended to further support refining the existing conceptual site model (CSM) by using measured concentrations of Table 3+ PFAS in the environment to identify sources and transport mechanisms that are the most likely to result in potentially complete exposure pathways for human receptors and rank these pathways based on potential intake. This information can then be used to focus future evaluations on pathways that are relevant to informing risk management decisions and excluding pathways that, albeit complete, are likely insignificant relative to overall exposure.

This SLEA considers relevant exposure scenarios under future potential conditions where Consent Order required air emission reduction targets have been achieved.

1.1 SLEA Objectives

The objectives of the SLEA are as follows:

1. Develop representative exposure point concentrations (EPCs) for HFPO-DA and other Table 3+ PFAS in offsite environmental media.
2. Develop estimates of average intake of HFPO-DA and other Table 3+ PFAS from relevant exposure pathways for potential human receptor populations in the vicinity of the Facility.
3. Develop estimated ranges of potential associated human health hazard, predicated on intake estimates by pathway and receptor population[5].
4. Identify and evaluate uncertainties associated with limitations in environmental data, and exposure assumptions in the context of the results of the SLEA intake and hazard characterizations to support site management decisions.

The methodology used in this assessment is consistent with North Carolina risk assessment practices and the United States Environmental Protection Agency's (USEPA) G*uidelines for Exposure Assessment* (USEPA, 1992) and *Draft Guidelines for Human Exposure Assessment* (USEPA, 2016).

The SLEA also supports the Groundwater Corrective Action Plan (CAP) required by Paragraph 16 of the executed Consent Order entered into court on February 25, 2019 and

---

[5] The SLEA hazard characterization uses the draft RfDo developed by the NC DHHS (2017), which underpins the State's provisional health goal for HFPO-DA in drinking water. The SLEA uncertainty assessment evaluates the implications for use of alternative toxicity criteria, such as the probabilistic RfDo developed by Thompson, et al. (2019) and the USEPA's draft RfDo (USEPA, 2018a). See Section 8.4.

signed by Chemours, the North Carolina Department of Environmental Quality (NCDEQ), and the Cape Fear River Watch (CFRW).

1.2 Overview of HFPO-DA

HFPO-DA is a human-made chemical produced at the Chemours Fayetteville Works facility in Bladen County, North Carolina. HFPO-DA is a six carbon, branched PFAS containing an ether bond (i.e., an oxygen atom linking two carbon atoms). HFPO-DA[6] is a clear, colorless liquid completely miscible with water (i.e., infinite solubility in surface water, groundwater, rainwater, leachate) and low octanol-water partitioning capacity (empirically estimated $\log K_{ow}$ of 4.24)[7]. Under normal environmental conditions, HFPO-DA exists as an anionic acid (2.8 acid dissociation constant [pKa])[8] (Hoke et al., 2016). Biodegradability test data (DuPont-A080558; Kaplan, 2010) indicate HFPO-DA is not readily biodegradable, with a half-life in soil, water, air, and sediment greater than 6 months (USEPA, 2018a). As such, HFPO-DA is expected to be relatively stable and persistent in the environment, and resistant to photolysis and hydrolysis (undergoing very slow hydroxyl radical catalyzed indirect photolysis).

Measured bioconcentration factors (BCFs) and bioaccumulation factors (BAFs) suggest that HFPO-DA has a low potential to bioaccumulate in biota. Multiple fish studies have confirmed BCFs of less than 3 and 30, based on exposure to 200,000 and 20,000 ng/L, and BCFs of 1 for higher concentrations (DuPont-A080560 2009; Hoke et al., 2016; Goodband, 2019). A recent study suggests that HFPO-DA does not have the capacity to bioaccumulate in some benthic fish species, based on treated food consumption over a 21-day exposure period (Hassell et al., 2019). Log BAFs calculated for carp were 0.86 for blood, 0.5 for liver and 0.61 for muscle. Tissue values indicate a BAF of less than 10 (Pan et al., 2017).

---

[6] HFPO-DA is used here to refer to: 2,3,3,3-tetrafluoro-2-(1,1,2,2,3,3,3-heptafluoropropoxy)-propanoic acid (CASN 13252-13-6), which has the chemical formula $C_6HF_{11}O_3$.
[7] K_{ow} is the octanol-water partitioning coefficient, the ratio of the equilibrium concentration of a dissolved chemical in a two-phase system of n-octanol and water. n-Octanol serves as a surrogate to biota lipids and K_{ow} is used as an indicator of a chemical's tendency to bioaccumulate in organisms.
[8] The pKa predicts that HFPO-DA will be in acid form (as a negative ion, or an anion) at a pH $\geq$ 2.8.

1.3 Document Organization

This document is organized as follows:

- Section 1, Introduction, presents the objectives of the SLEA and provides an overview of the Table 3+ PFAS.
- Section 2, Background, summarizes conditions in offsite areas in the vicinity of the Facility, focusing on those that are relevant to developing a CSM and conceptual exposure model (CEM).
- Section 3, Conceptual Exposure Model, identifies potentially complete exposure pathways by which human receptors may come into contact with Table 3+ PFAS in the environment.
- Section 4, Identification of Offsite Exposure Units, describes the organization of exposure units evaluated in the SLEA and the rationale for their identification.
- Section 5, Environmental Datasets and Exposure Point Concentrations, summarizes the data evaluated in the SLEA, including the sampling and analysis methods for data collection, and describes how data are used in the SLEA to quantify potential human exposure.
- Section 6, Intake Characterization, summarizes the methods for quantifying human exposure and compares the calculated intakes by exposure media for relevant populations and associated complete exposure pathways.
- Section 7, Provisional Hazard Characterization, presents a description of the methods and toxicological criteria used to derive estimated human health hazard quantitative point estimates for relevant populations and associated complete exposure pathways, related to HFPO-DA.
- Section 8, Uncertainty Assessment, identifies key uncertainties in the SLEA.
- Section 9, Conclusions, summarizes the findings of the SLEA.
- Section 10, References, presents the references used in the development of the SLEA Report.

2 BACKGROUND

The following section describes the physical setting and operational history of the Facility, as well as fate and transport considerations for HFPO-DA.

2.1 Facility Description

The Facility is located within a 2,177-acre property at 22828 NC Highway 87, approximately 15 miles southeast of the city of Fayetteville, NC along the Bladen-Cumberland county line. Figure 1 presents an overview of the Facility location and features. The Facility is bounded by NC Highway 87 to the west, the Cape Fear River to the east, and by undeveloped areas and farmland to the north and south. Willis and Georgia Branch Creeks, which are tributaries of the Cape Fear River, are located near the northern and southern property boundaries respectively, with the Georgia Branch Creek being offsite for its entire course (Geosyntec, 2019a).

2.2 Facility History

The Facility property was originally purchased by E.I. du Pont de Nemours and Company (DuPont) in 1970 and the first manufacturing area was constructed shortly thereafter. A former manufacturing area, used to produce nylon strapping and elastomeric tape, was sold in 1992. DuPont sold its Butacite® and SentryGlas® manufacturing units to Kuraray America Inc. (Kuraray) in June 2014 and subsequently spun off its specialty chemicals business into Chemours in July 2015. Presently, the Facility consists of five manufacturing areas used to produce specialty fluorinated monomers, the intermediates and starting materials thereof, fluorinated polymer initiators and processing aids, fluorinated polymer resin, polymer sheeting, and manufactured products. The five manufacturing areas shown in Figure 1 include: Chemours Monomers IXM; Chemours Polymer Processing Aid (PPA); Kuraray Trosifol®; Kuraray SentryGlas®; and DuPont Company polyvinyl fluoride (PVF) resin manufacturing unit. In addition to the manufacturing operations, Chemours operates two natural gas-fired boilers and a wastewater treatment plant, which treatment includes sanitary wastewaters from Chemours, Kuraray, and DuPont and process wastewaters from Kuraray and DuPont (Geosyntec, 2019a). Hazardous waste generated during manufacturing activities are managed at the Hazardous Container and Storage Area prior to shipment offsite for treatment, disposal, or recycling (Parsons, 2014).

2.3 Climate

The climate in Bladen County is characterized by relatively mild winters, hot summers, and abundant rainfall. According to the National Weather Service, average monthly temperatures range from a high of 91 degrees Fahrenheit (°F) in July to a low of 33°F in

January. Average monthly rainfall ranges from a high of 5.92 inches in July to a low of 2.65 inches in December (Parsons, 2014).

2.4 Topography

The developed portion (manufacturing area) of the Facility is located on a relatively flat topographic plateau at an approximate elevation of 145 feet above mean sea level and approximately 70 feet above the Cape Fear River floodplain. Surface topography generally remains flat to the west with a gentle increase of about 5 feet to a topographic divide near NC Highway 87. However, ground surface elevations decrease from the topographic plateau at the manufacturing area towards the Cape Fear River to the east as well as its tributaries, Willis Creek to the north and Georgia Branch Creek to the south. Topographic relief from the main manufacturing area decreases by approximately 100 feet in elevation towards the Cape Fear River bank to the east. Inclined topographic relief combined with overland flow and groundwater seeps have created natural drainage networks into the Cape Fear River (Geosyntec, 2019a).

2.5 Cape Fear River and Tributaries

The Cape Fear River and its entire watershed are located in the state of North Carolina. The Cape Fear River drains 9,164 square miles and empties into the Atlantic Ocean near the city of Wilmington, NC. The Facility is situated on the western bank of the Cape Fear River; it draws water from the Cape Fear River and historically returned over 95% of this water via Old Outfall 002 (now discontinued) after being used primarily as non-contact cooling water. Two lock and dam systems with United States Geological Survey (USGS) stream gauges are located downstream of the Facility: (1) W.O. Huske Lock and Dam, located 0.5 river miles downstream from the Facility (USGS 02105500); and (2) Cape Fear Lock and Dam #1, located 55 river miles downstream (USGS 02105769).

There are three perennial surface water features that are tributaries to the Cape Fear River at or adjacent to the Facility. To the north of the Facility is Willis Creek. To the south of the Facility is Georgia Branch Creek which confluences with the Cape Fear River approximately 7,500 feet south of the W.O. Huske Dam. Old Outfall 002, which currently conveys only surface water and groundwater to the Cape Fear River, is approximately 1,350 feet south of the W.O. Huske Dam (Geosyntec, 2019a). Additionally, in January 2019 three groundwater seep features were identified on the bluff slope leading from the Facility to the Cape Fear River. These seeps represent groundwater exiting the aquifer and forming channelized flows of water to the Cape Fear River.

2.6 Table 3+ PFAS and Fate and Transport Considerations

Onsite PFAS were released historically from the Facility from aerial emissions with resulting deposition and from direct process water releases to groundwater. Offsite soil and groundwater PFAS are solely from aerial emission releases based on an analysis of both groundwater flow directions (offsite residential areas are hydraulically isolated or upgradient of process water release areas) and PFAS signatures (Geosyntec, 2019c). In turn, constituents in soil may have contributed to constituents in groundwater through leaching and infiltration of the vadose zone and to vegetation through root uptake. Table 3+ PFAS constituents in surface water may have arisen through aerial deposition, discharge of Facility wastewaters, stormwater/surficial runoff during precipitation events, or discharge from groundwater to receiving surface water bodies at the groundwater-surface water interface. Surface water concentrations may have contributed to fish tissue concentrations through bioconcentration.

Table 3+ PFAS, including HFPO-DA, have been detected in soils on- and offsite, in groundwater on- and offsite, in surface water on- and offsite, and in offsite biota. Sources of PFAS for the various environmental media examined in this SLEA are summarized in the table below.

Environmental Media	Aerial Emissions and Deposition	Process Water Releases
Cape Fear River	✓	✓
Offsite Soil	✓	--
Offsite Groundwater	✓	--
Offsite Terrestrial Vegetation	✓	--
Offsite Biota (e.g., fish)	Uptake and Bioconcentration from Surrounding Media	

Pursuant to Consent Order Paragraph 27, Chemours funded a study analyzing the fate and transport of identified PFAS originating from the Facility in air, surface water, and groundwater (Geosyntec, 2019d). The findings of the study are summarized below.

PFAS are a group of man-made carbon-based chemicals composed of a fully or partially fluorinated chain of carbon atoms (referred to as a "tail") and a nonfluorinated, polar functional group (referred to as a "head") at one end of the carbon chain. Fluorination of the carbon chain renders it hydrophobic and lipophobic, while the polar head group is hydrophilic (Mueller and Yingling, 2018). Generally, PFAS vapor pressures are low and water solubilities are high. Most PFAS have one or more negatively charged head groups, so they are likely to be relatively mobile in the subsurface due to the affinity of the head group for water molecules (Mueller and Yingling, 2018).

Most Table 3+ PFAS, are fluoroethers: their structure includes two carbons connected by an oxygen atom – an ether bond. PFAS with ether bonds are expected to be less volatile and more soluble than non-ether PFAS of equivalent chain length due to the polar oxygen atoms included in their structures. Table 3+ PFAS contain at least one polar head group and many also contain additional polar head groups. The structural information for the Table 3+ PFAS is provided in Table 2.

Generally, Table 3+ PFAS are expected to be mobile in the environment given the presence of charged head groups and ether bonds, but they will experience some retardation. For some Table 3+ PFAS, mobility may be enhanced relative to straight-chain, non-ether PFAS by their branched structure and the presence of two charged head groups. The mobility of the Table 3+ PFAS will be retarded by various chemical processes but will likely have lower retardation than long-chain PFAS without ether bonds. Chemical processes expected to have the most impact on mobility are sorption to organic carbon and, in the unsaturated soil zone, preferential partitioning to the air water interface.

The tails of PFAS are made primarily of carbon atoms. They tend to be nonpolar, and so they tend to sorb to organic carbon species in soil and sediment (Higgins and Luthy 2006, Guelfo and Higgins, 2013). Because PFAS tails are also lipophobic, sorption to organic carbon tends to be weaker than that of alkanes. The sorption and retardation of PFAS will increase with increasing fluorinated tail length. For a given soil, sediment, or organic carbon type, the structure of the PFAS tail affects its interactions with organic carbon molecules. Branched isomers tend to have lower sorption affinity than linear isomers of equal chain length (Kärrman et al., 2011). Sorption of PFAS to charged particle surfaces in common soils and sediments is expected to be negligible relative to sorption to particulate organic carbon (Higgins and Luthy, 2006).

Current literature indicates that transformation of most PFAS in the environment is negligible. An important observed environmental transformation of PFAS has been the hydrolysis of some polyfluorinated precursors to form perfluorinated compounds (Mueller and Yingling, 2018) and the biotic degradation of trifluoroacetate (e.g., Visscher et al., 1994). Recently, researchers identified an Acidimicrobium microbial species that appears capable of defluorinating select PFAS (Huang and Jaffe, 2019). The ether and carbon-hydrogen bond components of the Table 3+ PFAS may be amenable to transformation reactions that degrade the tails of these compounds (e.g., Weber et al., 2017).

3 CONCEPTUAL EXPOSURE MODEL

Development of a CEM [conceptual exposure model] is recommended by USEPA (USEPA, 1989) to support interpretation of environmental data and inform site management decisions. The SLEA CEM identifies potentially complete exposure pathways by which human receptors could come in contact with Table 3+ PFAS in environmental media within the offsite Study Area. For an exposure pathway to be complete, the following five elements are necessary:

- a source or release from a source;
- a mechanism of release and transport;
- an exposure medium (i.e., point of contact) for potential receptors;
- an exposure route (e.g., ingestion); and,
- the presence of a receptor population (e.g., residential adult and child).

If an element of the CEM is missing, the exposure pathway is considered incomplete. For the purposes of the SLEA, source and release/transport mechanism(s) for PFAS are presumed to exist. As such, the SLEA focuses on characterizing exposure media, exposure routes, and human receptors for Table 3+ PFAS. Generally, intake of Table 3+ PFAS is only quantified for complete pathways but, in some instances for the purpose of informing site management decisions, intake is also quantified for pathways that are not reasonably anticipated to be complete (e.g., due to current or planned implementation of institutional controls).

The human health CEM is diagrammatically presented in Figure 2 and its elements are described below. The CEM reflects the current understanding of fate and transport mechanisms and exposure conditions in the vicinity of the Facility but may be updated as new information becomes available.

3.1 Offsite Receptor Populations

The Facility property encompasses 2,177 acres of relatively flat, undeveloped open land and woodland bounded by the Cape Fear River on the east, NC Highway 87 on the west, Willis Creek on the north, and farmland on the south (Figure 1). Based on the current Facility setting, including surrounding land uses, potential receptors for evaluation in the SLEA and the rationale for their inclusion are summarized below:

- Residents (Adult and Child). The nearest residence is approximately 1 km north of Facility manufacturing areas. North and northwest of the Facility, several residential neighborhoods occur within 5 km of the Facility.

- Farmers (Adult and Child). Farmers were identified as potential receptors based on the predominance of agricultural land use to the east, south, and west of the Facility.
- Gardeners (Adult and Child). Residents and farmers may garden on their properties to grow homegrown produce for personal consumption.
- Offsite workers (Adults only). Although residential and agricultural land uses predominate the areas surrounding the Facility, some commercial businesses are also present.
- Recreationalists (Adult and Child). The Cape Fear River may be used for recreational purposes, including canoeing and swimming.
- Recreational anglers (Adult and Child). The Cape Fear River and regional private ponds and lakes may be used for recreational purposes, including fishing.

3.2 Environmental Exposure Media and Routes

The SLEA focuses on evaluating the relative potential for intake based on direct and indirect contact with Table 3+ PFAS detected in environmental media from air deposition and from historical process water releases (i.e., via outfall releases and/or via migration of groundwater to Cape Fear River surface water adjacent to and downstream of the Site). This SLEA also considers ongoing and future stack emissions in light of stack control technologies, for instance the Thermal Oxidizer control technology is scheduled to be operational by December 31, 2019. Environmental investigations have detected Table 3+ PFAS in soil, groundwater, surface water, plants (non-edible), and fish in the vicinity of the Facility. Potential exposure media and routes evaluated in the SLEA are summarized below. Unless otherwise noted below, these media-specific complete exposure pathways are quantitatively evaluated herein. It is important to note that these are hypothetical exposure scenarios developed to evaluate the potential for exposure; in reality, some (or all) of these assumed exposure pathways may be incomplete for specific receptor populations.

- Offsite Surface Soil. Stack and fugitive process emissions to ambient air have resulted in historically-deposited PFAS in offsite soils, based on dispersion and deposition processes. The projected 99% reduction in Facility-wide air emissions of "GenX compounds" (as defined in the Consent Order) will significantly reduce continuing contribution to offsite surface soil and associated concentrations are expected to attenuate over time. Offsite residents, farmers, gardeners, and workers are assumed to be directly exposed to surface soil via incidental ingestion and dermal contact. As described in Section 8.3.1, dermal absorption studies with HFPO-DA indicate exposure via the dermal pathway is unlikely to be significant

(DuPont-25292, 2008); as such, dermal exposure to surface soil is discussed as part of the uncertainty assessment. Soil intake by offsite commercial workers is likely to be lower than that of other offsite populations (e.g., residents, farmers, and gardeners); therefore, offsite worker exposure to soil is qualitatively evaluated in the uncertainty assessment based on the results of receptors with greater exposure potential.

- Offsite Subsurface Soil. Table 3+PFAS present in offsite subsurface soils originate from aerial deposition followed by downward infiltration through the vadose zone (unsaturated zone). For most receptors, the potential for direct exposure to subsurface soil is incomplete and, relative to surface soil, would likely be insignificant. Therefore, surface soil conditions are relevant to informing risk management decisions. As such, direct contact with subsurface soil is semi-quantitatively evaluated as component of the SLEA uncertainty assessment.
- Offsite Groundwater. Table 3+ PFAS present in offsite groundwater originate from historically-deposited PFAS which have infiltrated from soils to groundwater. Table 3+ PFAS have been detected in groundwater used for drinking water in private wells within the vicinity of the Facility. Offsite residents, farmers, gardeners, and workers using well water for potable purposes are assumed to be exposed to historically-deposited PFAS via ingestion and dermal contact. Due to their limited dermal absorption efficiency (see Section 8.3.1), exposure to PFAS in water via dermal contact is considered an insignificant exposure pathway and, therefore, associated intake is qualitatively evaluated as a component of the uncertainty assessment. Irrigation-related contact represents a significantly lessened degree of exposure when compared to more frequent drinking water use. Thus, irrigation-related exposures are qualitatively evaluated as a component of the uncertainty assessment.
- Surface Water. Table 3+ PFAS present in offsite surface water, excluding Willis Creek and the Cape Fear River, stem from offsite aerial deposition, precipitation runoff, and groundwater discharge at the groundwater-surface water interface transporting historically-deposited PFAS to surface water bodies. Willis Creek and the Cape Fear River also include contributions from onsite, direct release sources (e.g., outfalls). Recreationalists have the potential to be exposed to Table 3+ PFAS in surface water (e.g., ponds and creeks near the Facility, Cape Fear River) via incidental ingestion and dermal contact (e.g., swimming, canoeing). Approximately 8 and 55 miles downstream of the Facility, respectively, surface water from the Cape Fear River is withdrawn and treated for use as drinking water at the Bladen Bluffs and Kings Bluff water treatment facilities. Offsite residents, farmers, gardeners, and workers are assumed to use

untreated Cape Fear River water collected from the intake points for potable purposes and, therefore, are assumed to be exposed to Table 3+ PFAS via ingestion and dermal contact. As with well water exposure scenarios, dermal contact intakes for surface water as a function of domestic water supply are insignificant and are qualitatively evaluated in the uncertainty assessment. Offsite worker exposure to surface water as drinking water is also qualitatively evaluated.

- Terrestrial Biota. Invertebrates and other terrestrial biota may potentially assimilate PFAS from soil or, in the case of plants, from soil, pore water, and wet and dry deposited particulates, by extension. As such, farmers and gardeners are assumed to be indirectly exposed to Table 3+ PFAS via consumption of plants and livestock. The SLEA quantitatively evaluates plant intake using biouptake models from the USEPA (2005); other consumable terrestrial biota (i.e., agricultural livestock and game species) are qualitatively evaluated as part of the uncertainty assessment.
- Fish Tissue. Aquatic species in the Cape Fear River and surrounding surface water bodies (e.g., local ponds) may assimilate PFAS from sediment, surface water, or food/prey items. As such, recreational anglers are assumed to be indirectly exposed to Table 3+ PFAS via consumption of fish fillets.

3.3 Complete Exposure Pathways

Receptor-exposure scenarios developed for the SLEA to quantitatively evaluate intake of historically-released Table 3+ PFAS from soil, homegrown produce, untreated well water, untreated surface water, and fish tissue are summarized below. For the well water-as-drinking water scenarios, a “current conditions” exposure was also quantified, which considered the requirements of the Consent Order for providing replacement drinking water and treatment systems. As noted above, these exposure pathways are assumed to be complete for the purposes of the SLEA but some or all related exposure pathways may be incomplete for an actual offsite receptor. For example, the SLEA assumes gardeners and farmers only consume fruits and vegetables that are homegrown whereas, in reality, most people also (or exclusively) consume store-brought fruits and vegetables grown in a variety of locations.

- Residents (Adult and Child): Surface soil via incidental ingestion; untreated well water as drinking water via ingestion; current conditions well water as drinking water via ingestion; and untreated Cape Fear River surface water from Bladen and Kings Bluff as drinking water via ingestion. Soil and drinking water exposure assumptions for residents are presented in Attachment F, Table F-2-1.

- Farmers (Adult and Child): Surface soil via incidental ingestion; untreated well water as drinking water via ingestion; current conditions well water as drinking water via ingestion; and, aboveground leafy vegetables (e.g., lettuce), aboveground fruits (e.g., tomatoes), and belowground vegetables (e.g., carrots) via ingestion. Soil, produce, and drinking water exposure assumptions for farmers are presented in Attachment F, Table F-2-2.

- Gardeners (Adult and Child): Surface soil via incidental ingestion; untreated well water as drinking water via ingestion; current conditions well water as drinking water via ingestion; and, aboveground leafy vegetables (e.g., lettuce), aboveground fruits (e.g., tomatoes), and belowground vegetables (e.g., carrots) via ingestion. Soil, produce, and drinking water exposure assumptions for gardeners are presented in Attachment F, Table F-2-3.

- Recreationalists (Adult and Child): Untreated surface water via incidental ingestion. Surface water exposure assumptions for recreationalists are presented in Attachment F, Table F-2-4.

- Recreational Anglers (Adult and Child): Fish tissue fillets via ingestion. Fish consumption exposure assumptions for Recreational Anglers are presented in Attachment F, Table F-2-5.

Additionally, the uncertainty assessment (Section 8.3.1) includes a qualitative or semi-quantitative evaluation of Table 3+ PFAS intake for: (i) direct exposure to subsurface soil by residents, farmers, and gardeners; (ii) use of groundwater as irrigation water by farmers and gardeners; (iii) consumption of livestock by farmers; (iv) direct exposure to surface soil and use of untreated well water and surface water as drinking water by offsite workers; and (v) dermal contact with soil, groundwater, and surface water by relevant receptors.

4 IDENTIFICATION OF OFFSITE EXPOSURE UNITS

The selection of SLEA exposure units (EUs) was premised on the concept that, based on aerial dispersion and deposition as well as direct discharge of waste and process waters, concentrations of Table 3+ PFAS in environmental media are likely to attenuate with distance from the Facility, particularly for well water and soil which are the primary offsite exposure media of interest. As such, the offsite study area was conceptualized as three concentric circles originating from the approximate center-point of the Facility that correspond to radial distances of 2.5, 5, and 10 km. These concentric circles were then bisected north-to-south and east-to-west to subdivide the offsite study area into northeast, southeast, southwest, and northwest quadrants. Additionally, the northeast direction quadrant corresponds to the dominant wind direction (ERM, 2018) and the EUs that comprise this quadrant (EUs 1, 5, and 9) capture the areas of likely highest historical aerial deposition to soil. Therefore, as shown in Figure 3, the upland EUs evaluated in the SLEA are:

- EU1: 2.5-km radius, northeast;
- EU2: 2.5-km radius, southeast;
- EU3: 2.5-km radius, southwest;
- EU4: 2.5-km radius, northwest;
- EU5: 5-km radius, northeast;
- EU6: 5-km radius, southeast;
- EU7: 5-km radius, southwest;
- EU8: 5-km radius, northwest;
- EU9: 10-km radius, northeast;
- EU10: 10-km radius, southeast;
- EU11: 10-km radius, southwest; and
- EU12: 10-km radius, northwest.

The Cape Fear River was also subdivided into multiple EUs, where:

- EU13: upstream locations;
- EU14: Facility-adjacent locations;
- EU15: locations approximately 4 miles downstream of the Facility;

- EU16: locations approximately 8 miles downstream of the Facility at Bladen Bluffs; and
- EU17: locations approximately 55 miles downstream of the Facility at Kings Bluffs.

Additionally, two ponds were designated as EUs:

- EU18: Pond 1 located in the northwest corner of the Facility; and
- EU19: Pond B located approximately 1 mile east-southeast of the Facility, on the east side of the Cape Fear River.

For each upland EU (EU1 through EU12), exposure to surface soil, untreated well water, current conditions well water (i.e., in consideration of the Consent Order requirements for replacement drinking water and treatment systems), and produce is quantitatively evaluated. For each Cape Fear River EU and the two Pond EUs, exposure to surface water is quantitatively evaluated. Fish tissue consumption is quantitatively at the Cape Fear River EUs 13 through 16 and onsite Pond 1 (EU18); fish tissue was not collected at Kings Bluffs (EU17) or offsite Pond B (EU19). Additionally, residential consumption of untreated surface water collected at the public water supply intakes located at Bladen Bluffs and Kings Bluffs, is quantitatively evaluated within the context of the SLEA.

5 ENVIRONMENTAL DATASETS AND EPCS

This section describes the SLEA datasets and EPC calculation methods. Media-specific EPCs are used to quantify intake as described in Section 7.

Analytical datasets evaluated in the SLEA are presented in Appendix B. Datasets for soil and fish tissue consist of samples collected between July and September 2019 per the SLEA Work Plan (Geosyntec 2019e). The dataset for surface water consists of samples collected between September 2017 and October 2019, including data collected per the SLEA Work Plan and downstream data reported by the NCDEQ and CFPUA. The SLEA relies upon well water data collected as part of ongoing offsite monitoring, using recent data collected between 2017 and 2019 to quantify potential intake.

EPCs were calculated on an EU-specific basis. When possible, EPCs based on the mean and 95% UCL concentrations are evaluated to provide a range of potential intake estimates where these EPCs are referred to herein as the central tendency exposure (CTE) and reasonable maximum exposure (RME), respectively. The mean and UCL concentrations were calculated using ProUCL Version 5.1; ProUCL outputs are provided as Appendix C. Media-specific considerations for EPC calculation are discussed in the subsections below.

5.1 Soil

The SLEA characterizes potential Table 3+ PFAS intake from exposure to offsite soil using data collected between July and September 2019. The goal of the soil sampling investigation was to characterize regional soil conditions in surficial and subsurface depth intervals for each of the 12 EUs, defined in Section 4 (Figure 3). The EUs were arrayed by quadrant and proximity, extending to a distance of 10 km from the approximate center-point of the Facility such that they range in size and include units that are very large (e.g., EUs 9, 10, 11, and 12). Soil datasets are described in Section 5.1.1. Soil EPCs are described in Section 5.1.2.

5.1.1 Soil Data

Surface soil is defined as 0 to 6 inches below ground surface (bgs). Surface soil sampling was conducted in consideration of ITRC's incremental sampling methodology (ISM), NCDEQ's recommendations for collecting composite soil samples from large areas without visible contamination (NCDEQ, 2015), and accessibility. In each EU, 30 discrete soil aliquots were collected and aggregated into a single composite sample submitted for laboratory analysis that is considered representative of the EU. A composite sampling approach was selected because it enables a more complete assessment of a large study area where discrete sampling was impractical (e.g., representativeness, coverage, schedule). The resulting EPC is considered characteristic of regional conditions and exposures within a given EU; however, as discussed further in the uncertainty assessment, it is acknowledged that composite sample EPCs may not be representative of a specific receptor's exposure.

Prior to field mobilization and in consideration of ISM guidance, each EU was gridded via ordinary or area-of-influence kriging to define 30 random sampling locations, or nodes. Areas that the project team knew to be inaccessible were excluded from the grid. Additional modifications to the sampling locations were necessary in the field due to access limitations, including lack of property owner consent, health and safety concerns, and physical barriers to access (e.g., dense vegetation). As a result, most sampling locations were selected in the field. Due to access limitations in the field, the majority of private property-based locations were excluded through potential lack of consent. Chemours was able to secure access to public rights-of-way through the NC Department of Transportation. As a result, some EUs reflect right-of-way-only data sampling locations. Sampling locations were recorded via global positioning system and are shown in Figure 4.

Surface soil aliquots were collected from 0 to 6-inches bgs using stainless steel bowls and spoons. Consistent with the SLEA Work Plan, individual surface soil sample aliquots were collected from 30 locations in each EU and were homogenized in the field and composited into a single sample for laboratory analysis, for a total of 12 surface soil samples. Subsurface soil samples were collected from a depth of 4 to 4.5 feet bgs using stainless steel hand augers. One discrete subsurface soil sample was collected from each EU for a total of 12 subsurface soil samples. In EUs 5, 7 and 8, the subsurface sampling location was selected at random from the 30 surface sampling locations. For the remaining EUs, collection of the subsurface soil sample was coordinated with installation of a groundwater monitoring well. For these EUs, the subsurface soil grab sample was preferentially collected from the borehole (and so is not paired with a discrete surface soil aliquot represented in the composite sample). In any case, for each EU, 30 surface soil aliquots were composited into one sample for laboratory analysis and one discrete subsurface soil sample was submitted for laboratory analysis.

Although the subsurface soil sample is a discrete grab sample, there are no significant concerns in comparison to the composite-based surface soil sample, on an individual EU basis. Subsurface soil direct contact is not a basis for quantitative evaluation in the exposure assessment, as the potential for direct contact exposure is significantly reduced when compared to surface soil complete exposure pathways. The subsurface soil sample provides an indication of the significance of vadose zone leaching potential but is not a significant line of evidence for use in predicting groundwater concentrations, as direct measurements in groundwater are available. As such, the subsurface soil data are not used to quantitatively assess leaching to groundwater.

Field personnel collected quality assurance/quality control (QA/QC) samples (i.e., duplicates, matrix spikes/matrix spike duplicates, and equipment blanks); however, in the interests of performing this SLEA in a timeframe capable of supporting the development of a CAP by December 31, 2019, replicate samples were not collected.

Composited surface soil samples and discrete subsurface soil samples were shipped under chain of custody to a TestAmerica analytical laboratory for analysis of Table 3+ PFAS per the SOP.

In Figure 4, surface soil sampling locations are shown, grouped by EU and presented in uniform color. Subsurface soil sampling locations are shown in white, irrespective of EU. As discussed above, 30 individual surface soil aliquots were composited into one composite sample for laboratory analysis. In three EUs (EUs 5, 7 and 8), Chemours collected a subsurface soil sample (4-4.5 ft bgs), co-located with a surface soil aliquot; these locations are designated by a crosshatched white circle in Figure 4. For the remaining EUs, Chemours collected a discrete subsurface soil sample (4-4.5 ft bgs), based on access, clearance, and the installation of a groundwater monitoring well. Specific sampling location outcomes are discussed, below:

- EU1: 2.5-km radius, Northeast Quadrant. Thirty surface soil aliquots were collected. Based on access restrictions in offsite areas, sampling coverage in EU1 was evenly split between three residential properties adjacent to Marsh Wood Lake and a public access roadway in the eastern portion of the EU. Fifteen surface soil samples were collected in the southeast corner of this EU, along a public roadway. Fifteen additional samples were collected from three private residential yards (five samples per residence) located adjacent to Marsh Wood Lake. A discrete subsurface soil sample (4-4.5 ft bgs) was collected from one of these residences, coincident with the installation of a monitoring well. The predominant air depositional pattern extends from the Facility to the northeast. The three residences adjacent to Marsh Wood Lake occur along this vector. A lower potential for deposition is associated with the sampling points in the southeast corner of EU1, providing a mix of representative soil conditions. The central area of EU1 is not well represented by the existing dataset, owing to access restrictions. A total of 31 soil samples were collected from 31 locations within this EU.
- EU2: 2.5-km radius, Southeast Quadrant. Thirty surface soil aliquots were collected. Based on access restrictions in offsite areas, sampling coverage is constrained in EU2 but can be considered complete, extending across the EU. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a

monitoring well installation, located at the approximate midpoint of the EU. A total of 31 samples were collected from 31 locations within this EU.

- EU3: 2.5-km radius, Southwest Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage in offsite areas is constrained in EU3 but can be considered complete, extending across the EU. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a monitoring well installation, located in the northwest quadrant of the EU. A total of 31 samples were collected from 31 locations within this EU.
- EU4: 2.5-km radius, Northwest Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is constrained in EU4 but can be considered complete, extending across the EU. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a monitoring well installation, located in the northeast quadrant of the EU. A total of 31 samples were collected from 31 locations within this EU.
- EU5: 5-km radius, Northeast Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is fairly well distributed across the EU and can be considered complete. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a surface soil sample aliquot, located on the southern border of the EU. A total of 31 samples were collected from 30 locations within this EU.
- EU6: 5-km radius, Southeast Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is constrained to the eastern and western areas of the EU, with the central area largely unaddressed. Nonetheless, the existing characterization is considered complete, and representative of conditions radiating from the source. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a monitoring well installation, located in the northwest quadrant of the EU. A total of 31 samples were collected from 31 locations within this EU.
- EU7: 5-km radius, Southwest Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is well distributed and can be considered complete in EU8, extending throughout the EU. One co-located subsurface soil sample (4-4.5 ft bgs) was collected coincident with a surface soil aliquot location, located in the southeast quadrant of the EU. A total of 31 samples were collected from 30 locations within this EU.
- EU8: 5-km radius, Northwest Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is well distributed and can be considered complete in EU7, extending throughout

the EU. One co-located subsurface soil sample (4-4.5 ft bgs) was collected coincident with a surface soil aliquot location, located on the southeast border of the EU. A total of 31 samples were collected from 30 locations within this EU.

- EU9: 10-km radius, Northeast Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is fairly well distributed across the EU and can be considered complete. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a monitoring well installation, located in the northwest quadrant of the EU. A total of 31 samples were collected from 31 locations within this EU.
- EU10: 10-km radius, Southeast Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is fairly well distributed across the EU and can be considered complete. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a monitoring well installation, located in the central area of the EU. A total of 31 samples were collected from 31 locations within this EU.
- EU11: 10-km radius, Southwest Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is fairly well distributed across the EU and can be considered complete. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a monitoring well installation, located in the southeast quadrant of the EU. A total of 31 samples were collected from 31 locations within this EU.
- EU12: 10-km radius, Northwest Quadrant. Thirty surface soil aliquots were collected. Targeting public access roadways, sampling coverage is in offsite areas is fairly well distributed across the EU and can be considered complete. One discrete subsurface soil sample (4-4.5 ft bgs) was collected coincident with a monitoring well installation, located in the central area of the EU. A total of 31 samples were collected from 31 locations within this EU.

5.1.2 Soil EPCs

One composite surface soil sample and one discrete subsurface soil sample were collected from each upland EU. Hence, soil CTE and RME EPCs are equivalent to single sample, maximum detected concentrations. Soil EPCs are summarized in Table F-3-1.

Of the 20 Table 3+ constituents, only two were detected in soil – HFPO-DA, which was detected in two surface and three subsurface samples, and perfluoro(3,5-dioxahexanoic) acid (PFO2HxA), which was detected in two surface samples and one subsurface sample.

As discussed above, subsurface soil data are not used in the intake characterization or provisional hazard characterization. However, potential intake of Table 3+ PFAS in subsurface soil is discussed as part of the uncertainty assessment.

5.2 Well Water

The SLEA assesses untreated well water as drinking water, via domestic water usage, based on available data in the upland EUs (i.e., EU1 through EU12). As part of the Consent Order implementation, Chemours is required to offer replacement drinking water (in the form of public water or whole building filtration systems) when private wells have HFPO-DA detected above 140 ng/L. When any individual PFAS listed in Consent Order Attachment C exceeds 10 ng/L or when total PFAS listed in Consent Order Attachment C exceed 70 ng/L, Chemours is required to offer residents or other persons up to three under-the-sink reverse osmosis drinking water systems. Chemours is required to offer temporary replacement water supplies (i.e., bottled water) to residents or other persons qualifying for a filtration or reverse osmosis system until these systems have been provided. Hence, untreated well water data are not representative of current conditions and results in SLEA intake and hazard estimates that are conservative (i.e., health protective). Therefore, the SLEA also includes a "current conditions" evaluation based on drinking water concentrations of 10 ng/L of HFPO-DA and 70 ng/L of total PFAS. These assumed current conditions concentrations represent the maximum concentrations where the Consent Order does not require treatment. However, even this evaluation likely overestimates EU-wide intake and hazard as PFAS are uniformly reported as non-detect in household drinking water where filtration or under-the-sink reverse osmosis drinking water systems have been provided by Chemours.

The untreated well water datasets are described in Section 5.2.1. Untreated well water EPCs are described in Section 5.2.2.

5.2.1 Well Water Data

The SLEA characterizes potential intake of Consent Order Attachment C PFAS[9] from drinking water using untreated data collected from offsite private drinking water wells samples (i.e., mid- and post- filtration results were excluded). PFAS analytical groundwater data for evaluation in the SLEA were compiled from the Chemours Locus Environmental Information Management system (EIM), which includes a large dataset

[9] Well water samples collected as part of ongoing monitoring are analyzed for the 10 Table 3+ PFAS compounds specified in Attachment C of the Consent Order. Table F-1 identifies the target analytes associated with each SOP.

of well data from the offsite study area (over 1,000 wells), particularly for downgradient wells located north of the Facility.

Offsite private drinking water wells are screened in both the Surficial and Black Creek Aquifers, based on a review of resident-reported well depths and offsite geological well records retrieved from www.ncwater.org. There were 55 wells with lithology and geophysical data available in the vicinity of the Facility. These wells were sampled for up to 48 PFAS compounds using various analytical laboratories and methods and not all Table 3+ PFAS were analyzed in each sample.

Locations of the wells sampled in 2017 and 2019, which were included in the SLEA, are presented in Figure 5.

5.2.2 Well Water EPCs

For each well, only the most recent sampling data for Table 3+ analytes were evaluated in the SLEA. Where duplicate data exists for a well/analyte pair, the highest concentration result was retained for analysis. Data were segregated by EU prior to EPC calculation. A mean and 95% UCL concentration were calculated to represent the CTE and RME EPCs, respectively, for each EU using ProUCL Version 5.1 (USEPA, 2015a); if ProUCL could not reliably calculate a UCL or the recommended UCL exceeded the maximum detected concentration, the maximum detected concentration was selected as the RME EPC. ProUCL output is provided in Appendix C.

Untreated well water EPCs are presented in Appendix F, Table F-3-2. Of the 11 Table 3+ constituents listed on Attachment C and analyzed for in untreated well water, nine (9) were detected in at least one EU. Generally, concentrations in EUs 1 through 4 are higher than those in other EUs, indicating an attenuation of concentrations with distance from the Facility, which is consistent with the CSM. Additional spatial analysis of well data is presented in the Paragraph 19 *On and Offsite Assessment Report* (Geosyntec, 2019c).

5.3 <u>Surface Water</u>

The SLEA characterizes potential PFAS intake from surface water using data collected between 2017 and 2019, as described below. Surface water data were used to calculate EPCs for recreational swimming exposure conditions for four locations in the Cape Fear River, one onsite pond, and one offsite pond. Cape Fear River EPCs were developed for untreated surface water samples collected upstream, adjacent to, and downstream of the Facility, and used to evaluate recreational exposure. Cape Fear River EPCs were also developed for untreated downstream surface water collected from public supply intakes at Bladen Bluffs and Kings Bluffs to conservatively evaluate potable use exposure. EPCs representative of local ponds were developed on a pond-specific basis; only recreational exposures (e.g., fishing, swimming) were evaluated for the ponds. Surface water datasets are described in Section 5.3.1. Surface water EPCs are described in Section 5.3.2.

5.3.1 Surface Water Data

The SLEA considered surface water data collected from the locations shown in Figure 7 during the following sampling events:

- September 2017 Local Program surface water sampling conducted per the *Cape Fear River Surface Water Sampling Plan* (Parsons, 2017a);
- May 2018 Local Program surface water sampling conducted per the *Additional Cape Fear River Surface Water Sampling Plan* (Geosyntec, 2018a);
- June 2018 Regional Program surface water sampling conducted per the *Addendum to Additional Cape Fear River Surface Water Sampling Plan* (Geosyntec, 2018b);
- October and December 2018 Post-Florence surface water sampling conducted per the *Post Hurricane Florence Sampling Plan* (Geosyntec, 2018c);
- Spring (February, May, and June) 2019 surface water sampling conducted per the *Seeps and Creeks Investigation Report* (Geosyntec, 2019b); and
- Summer 2019 SLEA surface water sampling conducted per the *SLEA Work Plan* (Geosyntec, 2019e).

Results of pre-SLEA sampling events were reported in: C*ape Fear River Surface Water Sampling Memorandum* (Parsons, 2017b); *Assessment of the Chemical and Spatial Distribution of PFAS in the Cape Fear River* (Geosyntec, 2018d); and *Post Hurricane Florence PFAS Characterization Report* (Geosyntec, 2018e). A summary of these sampling events is provided below.

Local sampling programs conducted by Parsons in September 2017 and May 2018 focused on portions of the Cape Fear River directly upstream, adjacent to, and downstream of the Facility (Geosyntec, 2018d). The associated surface water sampling locations along the Cape Fear River included Cape Fear River-01 (CFR-01) through CFR-09. At each surface water sampling location, four samples were collected along an east-west transect to assess the lateral and vertical concentration distributions in the Cape Rear River (Figure 6)[10]. Samples collected in the September 2017 and May 2018 events

[10] Transect samples are: (i) West, located 25% of the distance across the channel from the west shore, 1-foot below water surface; (ii) Center Top, located in the middle of the channel, 1-foot below water surface; (iii) Center Middle, located in the middle of the channel, halfway between surface and river bottom; and (iv) East, located 25% of the distance across the channel from the east shore, 1-foot below water surface.

were analyzed for perfluorinated carboxylic acids, perfluorosulfonic acids, and HFPO-DA (Geosyntec, 2018d).

A regional sampling program was performed in June 2018 by Parsons to characterize PFAS distribution from the confluence of the Deep and Haw Rivers [River Mile (RM)-0] to the Kings Bluff Intake Canal, where the City of Wilmington and the Counties of Pender and Brunswick draw water (RM-132). A total of 16 surface water samples were collected from discrete locations along the Cape Fear River. To the greatest extent practicable, samples were collected from the middle depth of the water column at the thalweg, i.e., the deepest portion of the river channel. The associated sample names indicate the miles from the start of the Cape Fear River and are denoted by RM-X. Samples were analyzed according to Method 8321, Method 537, and Method Table 3 SOP (the Table 3+ method was not yet developed at the time of analysis). Some Regional Program sampling locations are co-located with those from the Local Program sampling locations, for example RM-66/CFR-01 and RM-76/CFR-05 (Geosyntec, 2018d).

An assessment was conducted in October and December of 2018 to assess the effect of Hurricane Florence on the distribution of PFAS in the river (Geosyntec, 2018c). As part of the assessment, the following five (5) surface water samples were collected from the middle of the Cape Fear River: three upstream locations (RM-60, CFR-03, RM-76) and two downstream locations (RM-83 and RM-132). Samples were analyzed according to Method 537, Method Table 3 SOP, as well as Method Table 3+ SOP by the Chemours Fluoroproducts Analytical Group.

In the spring of 2019, 14 additional samples were collected from the middle of the Cape Fear River at RM-56, RM-68, RM-76, RM-84, and RM-132 (the last two locations correspond to the intakes for Bladen and Kings Bluffs, respectively). Samples were analyzed according to Method 537 Modified and Method Table 3+ SOP.

In support of the SLEA, additional surface water samples were collected in July and September 2019 from the Cape Fear River (EU14), an onsite pond (EU18 "Pond 1"), and an offsite pond (EU19 "Pond B"). At CFR-04 and CFR-07, four (4) samples were collected along an east-west transect as described in the SLEA Work Plan (Geosyntec, 2019e). Four (4) surface water samples were collected from onsite "Pond 1" located in the northwest portion of the Facility. Three (3) surface water samples were collected from offsite "Pond B" located 1 mile east of the Facility (east of the Cape Fear River). Surface water samples using a peristaltic pump, new dedicated high-density polyethylene (HDPE) tubing, and dedicated silicone tubing for the pump head at each location. In the Cape Fear River, the tubing was lowered to the Work Plan-specified sampling depth below the water surface using an anchor weight and the tubing positioned to point upwards; in the ponds, the tubing was lowered to the approximate middle depth of the surface water column. Surface water was pumped directly from submerged tubing through a peristaltic pump into new 250-milliliter HDPE bottles. Samples were shipped on ice via chain of custody for analysis via Method Table 3+ SOP (Table 1).

Finally, additional untreated (raw) surface water data from public intakes located at Bladen Bluffs and Kings Bluffs were obtained from a NCDEQ website[11] and from the Cape Fear Public Utility Authority (CFPUA) website[12], respectively.

5.3.2 Surface Water EPCs

Surface water data were segregated as follows to develop EPCs representative of recreational exposure at the following EUs:

- EU13, Cape Fear River Upstream: CFR-01/RM-66, CFR-02, CFR-03, RM-56, RM-60, and RM-68;
- EU14, Cape Fear River Facility-adjacent: CFR-04, CFR-05/RM-76, CFR-06, and CFR-07;
- EU15, Cape Fear River Downstream (4 Miles): CFR-09;
- EU16, Cape Fear River Downstream (8 Miles): RM-84, CFR-BLADEN, and NCDEQ Bladen Bluffs raw (untreated) water data;
- EU17, Cape Fear River Downstream (55 Miles): RM-132, CFR-KINGS, and CFPUA Sweeney raw (untreated) water data;
- EU18, Pond 1 (onsite): Pond-1-SE, Pond-1-NE, and Pond-1-NW; and
- EU19, Pond B (offsite): Pond-B-West, Pond-B-East, and Pond-B-South.

Surface water data were segregated as follows to develop EPCs representative of potential potable use:

- EU16, Cape Fear River Downstream (8 Miles): NCDEQ Bladen Bluffs raw (untreated) water data; and
- EU17, Cape Fear River Downstream (55 Miles): CFPUA Sweeney raw (untreated) water data.

The surface water dataset includes samples collected between July 2017 and October 2019. Data were reviewed to identify potential seasonal or annual concentration trends. Concentrations were variable but no trends were apparent. As such, 2017 to 2019 river water data were compiled for each EU to develop recreational use EPCs. Additionally, at Bladen and Kings Bluffs, which correspond to public water supply intake points, water

---

[11] https://deq.nc.gov/news/key-issues/genx-investigation
[12] https://www.cfpua.org/692/Drinking-Water-Quality

data reported by the NCDEQ for 2017 and CFPUA for 2018 and 2019 were used to develop potable use EPCs.

EPCs for the CTE and RME scenarios correspond to mean and 95% UCLs, respectively. Within the available historical datasets, detection limits were often not reported. As such, non-detect results were excluded rather than replaced with a surrogate value (e.g., zero or a more recent RL) to retain the conservative nature of the SLEA. To maintain consistency between EPC calculation methods for surface water, only detected values were used at each EU.

Surface water EPCs for the Cape Fear River, onsite pond, and offsite pond sampling locations are presented in Appendix F, Table F-3-4.

5.4 Fish

The SLEA characterizes potential intake of Table 3+ PFAS from recreational fish consumption using tissue samples collected between July and September 2019. Fish collection locations are shown in Figure 7 and color-coded by genus. Fish tissue data are described in Section 5.4.1. Fish tissue EPCs are described in Section 5.4.2.

5.4.1 Fish Tissue Data

In support of the SLEA, fish fillets were collected from five sampling points within the Cape Fear River: (i) 10 miles upstream of the Facility (RM-68) at EU13, which, relative to the distance from the Facility, far exceeds the expected home range for recreational sport fish targeted by local anglers (Lewis and Flickinger, 1967); (ii) adjacent to the Facility (CFR-05 and CFR-06) at EU14, (iii) 4 miles downstream of the Facility (CFR-09) at EU15, and (iv) 8 miles downstream of the Facility (Bladen Bluffs) at EU16. Fish fillets were also collected from onsite Pond 1 (EU18). Fish were not collected from Kings Bluffs (EU17), which is 55 miles downstream, or offsite Pond B (EU19), which is stocked with fish by the private owner.

Fish were collected by traditional rod-and-reel methods. Fish selected for chemical analysis were filleted in the field and fish fillets (i.e., muscle tissue) were preserved on ice and submitted to TestAmerica under chain of custody for analysis of PFAS per the Table 3+ SOP. Species selected for chemical analysis are summarized below by sampling location.

- EU13, Cape Fear River Upstream (RM-68). Five (5) fillet samples were collected from the upstream EU. One sample was collected from each of the following specimens: one flathead catfish (*Pylodictis olivaris*), one channel catfish (*Ictalurus punctatus*), one blue catfish (*Ictalurus furcatus*), and two largemouth bass (*Micropterus salmoides*). HFPO-DA and Table 3+ PFAS were not detected in EU13 fish fillet samples.

- EU14, Cape Fear River Facility-adjacent (CFR-06 and CFR-07). Seven (7) fillet samples were collected adjacent to the Facility. One sample was collected from each of the following specimens: one flathead catfish, one channel catfish, four blue catfish, and one largemouth bass. HFPO-DA was not detected at CFR-06 or CFR-07. Table 3+ PFAS were not detected in with the exception of perfluoromethoxypropyl carboxylic acid (PMPA) in three samples and perfluoro(3,5,7,9-tetraoxadecanoic) acid (PFO4DA) in one sample. Relative to the Huske Dam, four (4) specimens were collected upstream and three (3) were collected downstream. Based on these samples, the presence of the dam does not appear to be influencing fillet concentrations; therefore, for the purposes of SLEA EPC calculation, these samples were grouped together.
- EU15, Cape Fear River Downstream (CFR-09). Three (3) fillet samples were collected from CFR-09, which is located approximately 4 miles downstream of the Facility. One sample was collected from a largemouth bass and two samples were collected from blue catfish (separate specimens). HFPO-DA was not detected in the CFR-09 samples. PMPA was detected in one sample and PFO4DA was detected in two samples.
- EU16, Cape Fear River Downstream, Bladen Bluffs. Eight (8) fillet samples were collected from the Bladen Bluffs EU, which is located approximately 8 miles downstream of the Facility. One sample was collected from each of the following specimens: one bluegill sunfish (*Lepomis macrochirus*), one channel catfish, one largemouth bass, and five redbreasted sunfish (*Lepomis auratus*). Target PFAS were detected in six of the eight samples. perfluoro-1-methoxyacetic acid (PFMOAA) was the most frequently detected PFAS, with reported detections in five samples. HFPO-DA was detected in three samples and PFO4DA, perfluoro-3,5,7,9,11-pentaoxadodecanoic acid (PFO5DA), and R-EVE were detected in one sample each.
- EU18, Onsite Pond 1. Three (3) fish fillet samples were collected from onsite Pond 1. These samples were collected from three largemouth bass. HFPO-DA and Table 3+ PFAS were not detected in two of the three samples. In the third sample, PFO4DA and PMPA were detected.

In total, six (6) Table 3+ PFAS were detected in fish fillets. Concentrations were reviewed to identify potential concentration trends. Four of the six detected PFAS were only detected in samples collected from Bladen Bluffs, including HFPO-DA. PFO4DA was detected in onsite Pond 1, Facility-adjacent, and downstream samples; the highest concentration was reported at Bladen Bluffs and it exceeded onsite and Facility-adjacent concentrations by two or more orders of magnitude. PMPA was detected in onsite Pond 1, Facility-adjacent, and CFR-09 samples but not Bladen Bluffs samples; no concentration gradient was apparent for the detections. Detections occurred in multiple species and inspection of the data did not indicate a relationship to trophic level.

5.4.2 Fish Tissue EPCs

EPCs for the CTE and RME scenarios generally correspond to mean and 95% UCL concentrations calculated in ProUCL, respectively. However, based on the limited number of detections, EU-specific UCLs could not be calculated for some PFAS. In these instances, EPCs for the RME scenario correspond to maximum detected concentrations.

Fish fillet EPCs for the Cape Fear River and Pond 1 sampling locations are presented in Appendix F, Table F-3-5.

5.5 Homegrown Produce

5.5.1 Homegrown Produce Data

Due to seasonal limitations, harvest-ready produce could not be collected in the vicinity of the Facility. As such, the SLEA characterizes intake of Table 3+ PFAS from homegrown produce consumption using modeled concentrations in aboveground leafy vegetables (e.g., lettuce), aboveground fruits (e.g., tomatoes), and belowground vegetables (e.g., carrots).

5.5.2 Homegrown Produce EPCs

Produce EPCs were estimated using equations presented in the USEPA's 2005 *Human Health Risk Assessment Protocol for Hazardous Waste Combustion Facilities* (HHRAP). These equations consider bioconcentration of HFPO-DA from surface soil (via root uptake) and air (via particulate deposition and absorption). The produce exposure assessment is limited to HFPO-DA based upon its reliance on physicochemical parameters for modeling plant biouptake and Facility-specific deposition data. The HHRAP equations, inputs, and outputs are presented in Appendix E and discussed below.

Study area-specific inputs to the HHRAP equations are limited to surface soil EPCs and particulate emission and deposition rates; otherwise, inputs are based on USEPA recommendations or the primary literature. Surface soil EPCs, which are presented in Table F-4-1, were derived from data collected in September and October 2019 (i.e., per the SLEA Work Plan); soil EPCs were combined with the bioconcentration factors derived in Table E-1 to estimate produce EPCs as a result of root uptake. As with soil, a single EPC is used for the CTE and RME produce exposure estimates (Table F-4-5).

Particulate emission and deposition rates were developed from a regional deposition model developed by Chemours for emissions of HFPO-DA from both point and fugitive sources identified at the Facility. The eight (8) sources include the Vinyl Ethers North

Division, Vinyl Ethers South, and PPA Process Stacks and associated fugitive emissions, as well as the Polymers Process and Semi-Works Process Stacks. The deposition model used the latest versions of the regulatory dispersion model and supporting programs of AERMOD (version 1621r), AERMAP (version 11103), and BPIP (version 04274), and local meteorological data collected from 2012 through 2016 that was pre-processed for AERMOD by the NCDEQ. Chemours previously presented the deposition modeling results in the 2018 document, *Modeling Report: HFPO-DA Atmospheric Deposition and Screening Groundwater Effects, Fayetteville Works Facility, Fayetteville, NC* (ERM, 2018).

For the purposes of the SLEA and to focus the CAP on future conditions, the model was refined to account for planned stack emissions control measures, including a thermal oxidizer, that will reduce aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, and expected comparable reductions for other PFAS. Wet and dry deposition flux estimates for HFPO-DA were extracted from the refined model for multiple points within each EU. Using these data, an average and maximum flux were calculated (Table E-1 of Appendix E). The average and maximum flux estimates were combined with the projected 2020 Facility-wide emissions rate for HFPO-DA (Table D-1 of Appendix D).

5.6 Data Quality

Analytical data were reviewed using the Data Verification Module (DVM) within the EIM system, which is a commercial software program used to manage data. Following the DVM process, a manual review of the data was conducted. The DVM and manual review results were combined in a data review narrative report for each set of sample results, which is consistent with Stage 2b of the USEPA's *Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use* (USEPA, 2009). The narrative report summarizes which samples were qualified (if any), the specific reasons for the qualification, and any potential bias in reported results. The data usability, in view of the project's data quality objectives (DQOs), was assessed and the data were entered into the EIM system. The data were evaluated by the DVM against the following data usability checks:

- Hold time criteria;
- Field and laboratory blank contamination;
- Completeness of QA/QC samples;
- Matrix spike/matrix spike duplicate recoveries and the relative percent differences (RPDs) between these spikes;
- Laboratory control sample/control sample duplicate recoveries and the RPD between these spikes;

- Surrogate spike recoveries for organic analyses; and
- RPD between field duplicate sample pairs.

Results are presented in Appendix B with validator flags. The "J" and "UJ" flagged results indicate usable data, which should be considered as quantitatively estimated. In other words, the results are not necessarily within the laboratory's criteria for accuracy and precision of the test method employed, but in the reviewer's professional judgment are usable. Laboratory reports and data review narratives for drinking water samples collected prior to the Consent Order were included in reports prepared by Parsons (Parsons, 2017c, 2018 a, b); for samples collected after the Consent Order, the information is submitted electronically to NCDEQ on a routine basis. Laboratory reports and data review narratives for other media are provided as Appendix E to the Ecological SLEA (Geosyntec, 2019f).

6 INTAKE CHARACTERIZATION

Intake of PFAS was quantified as an average daily intake (ADI), expressed in units of milligrams of constituent per kilogram of body weight per day (mg/kg-day). Intake was calculated for each route and then summed by exposure medium (e.g., soil, drinking water). Total intakes for each receptor from relevant exposure media in a given EU were also calculated. For residents, farmers, gardeners, and recreationalists, two age groups were considered: a child age 0 to 6 years and an aggregated, age-adjusted child/adult receptor, reflective of 0 to 26 years of age.

6.1 Intake Equations and Inputs

The equations used to calculate intake are based on USEPA guidance, including the *Risk Assessment Guidance for Superfund* (USEPA, 1989); and the *Regional Screening Levels User's Guide* (USEPA, 2019a). Intake assumptions were developed based on USEPA guidance, including the *Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors* and associated updates (USEPA, 2014; 2015b) and the *Exposure Factors Handbook* and associated updates (USEPA, 2011; 2017; 2018b, c; 2019b). Receptor-specific inputs and equations are presented in Appendix F, Tables F-2-1 through F-2-5. EPCs are presented in Appendix F, Tables F-3-1 through F-3-5.

6.2 Intake Characterization Results

Tables F-4-1 through F-4-10 of Appendix F present the PFAS-specific intake calculations for each receptor-EU combination. Intake of total Table 3+ PFAS (i.e., the sum of detected Table 3+ PFAS) is presented in Table F-5-1 (upland EUs), Table F-5-2 (Cape Fear River and pond EUs), and Table F-5-3 (Cape Fear River surface water intake points). The intakes are summarized below, focusing on the RME exposure scenario.

As described in the Section 1 of this SLEA, the results of the intake characterization should be reviewed in consideration of the following:

- The SLEA drinking water intake estimates in EU1 through EU12 are initially calculated based on untreated well water which, in many cases, is not representative of current drinking water conditions. While ingestion of untreated well water as drinking water is the most significant complete intake pathway and contributor to hazard, Consent Order Attachment C PFAS are uniformly reported as non-detect in household drinking water where filtration or under-the-sink reverse osmosis drinking water systems have been provided by Chemours. Hence, the SLEA intake estimates based on untreated well water are conservative relative to current conditions.

- Chemours is taking action to reduce air emissions of PFAS from the Facility, including installation of a Thermal Oxidizer that will dramatically reduce aerial PFAS emissions from the Site, with reduction of aerial HFPO-DA emissions by 99% starting in January 2020 compared to 2017 baseline, and expected comparable reductions for other PFAS. With a reduction in air emissions, associated soil and groundwater concentrations (and, by extension, well water) will attenuate over time, as will contributions to other receiving media, such as surface water and recreational fish species.

6.2.1 Upland EUs

The results of the intake characterization for residents, farmers, and gardeners potentially exposed to Table 3+ PFAS in soil, homegrown produce, and untreated drinking water are summarized in Table F-5-1. Across all upland EUs (i.e., EU1 through EU12) for CTE and RME exposure scenarios, drinking water consumption, assuming untreated drinking water, accounted for 97% or more of total intake.

The RME range of intake estimates for each exposure medium was as follows:

- Untreated Well Water: 6.1E-06 to 4.7E-04 mg/kg-day
- Homegrown Produce: 7.7E-16 to 6.2E-06 mg/kg-day
- Surface Soil: 1.4E-09 to 6.3E-08 mg/kg-day

As discussed throughout this document, the use of untreated well water to calculate domestic use substantially overstates the current potential for exposure on a population and individual basis. The sum of RME EPCs for Table 3+ PFAS listed on Attachment C in untreated well water ranged from approximately 180 ng/L to 9,500 ng/L whereas under current conditions and per the requirements of the Consent Order, concentrations in the monitoring well network are presumed to range from non-detect (i.e., where treatment systems were installed) to 70 ng/L (i.e., the maximum concentration for which a treatment system would not be required by the Consent Order).

Table F-5-1 includes an RME intake estimate based on a PFAS concentration of 70 ng/L, which is the maximum EPC for drinking water wells in EU1 through EU12 that is reasonably anticipated under current conditions. The range of intakes under this assumed current conditions scenario was as follows (but may be as low as zero):

- Current Conditions Well Water: 2.4E-06 to 3.5E-06 mg/kg-day

6.2.2 Cape Fear River and Pond EUs

The results of the intake characterization for recreationalists potentially exposed to Table 3+ PFAS in surface water and fish tissue fillets from the Cape Fear River, onsite Pond 1, and offsite Pond B are summarized in Table F-5-2. The lowest intakes were associated with the upstream EU where Table 3+ PFAS were not detected in fish tissue. The highest intakes were associated with consumption of fish caught at Bladen Bluffs.

The range of RME intake for Facility-adjacent and near-downstream EUs (i.e., excluding Bladen and Kings Bluff) for each exposure medium was as follows:

- Surface Water: 7.3E-08 to 3.1E-06 mg/kg-day
- Fish Fillets: 1.1E-07 to 2.1E-06 mg/kg-day

The range of RME intake for Bladen and Kings Bluffs for each exposure medium was as follows:

- Surface Water: 1.1E-07 to 7.4E-07 mg/kg-day
- Fish Fillets (Bladen Bluff): 2.7E-05 to 4.7E-05 mg/kg-day

The contribution from fish and surface water to total intake varied by EU, and apparent differences may be attributable to the low number of detections, differences in detection capabilities for surface water and animal tissue, and the exclusion of non-detect results from the surface water EPC calculations (see Section 8.2.4).

6.2.3 Surface Water Intake Points

The results of the intake characterization for residents potentially exposed to HFPO-DA in untreated surface water at the public supply intake points at Bladen Bluffs (EU16) and Kings Bluffs (EU17) are summarized in Table F-5-3. These data were reported by NCDEQ and CFPUA. Total intake of HFPO-DA from residential consumption of untreated river water from Bladen Bluffs was approximately an order of magnitude higher than intake from Kings Bluffs. Of the Table 3+ compounds, only HFPO-DA was analyzed for at Bladen Bluffs and nine Table 3+ compounds were analyzed for at Kings Bluffs; as such, a total PFAS intake comparison could not be made between the two EUs. The range of RME intakes was as follows:

- Bladen Bluffs (HFPO-DA): 1.2E-05 to 1.8E-05 mg/kg-day
- Kings Bluffs (HFPO-DA): 6.4E-07 to 9.2E-07 mg/kg-day
- Kings Bluffs (Table 3+ PFAS): 3.5E-06 to 5.0E-06 mg/kg-day

7 PROVISIONAL HAZARD CHARACTERIZATION

The purpose of the SLEA is to assess which complete exposure pathways of Table 3+ PFAS are likely the most significant contributors of overall human exposure on a regional basis. The relative ranking of exposures resulting from the SLEA can be used to inform risk management decisions and exclude pathways that, albeit potentially complete, are insignificant relative to overall exposure potential.

In addition to providing a relative ranking of exposure pathways, the estimated intakes of HFPO-DA were also used to calculate provisional quantitative estimates of potential hazard. The hazard characterization is limited to an assessment of HFPO-DA based on the current availability of toxicity criteria, which are described in Section 7.1. The methods used to quantify potential hazard are described Section 7.2. The results of the provisional hazard characterization are presented in Section 7.3.

7.1 HFPO-DA Toxicity Criteria

The SLEA provisional hazard characterization is based on the RfDo of 1E-04 mg/kg-day adopted by the NC DHHS. There are other published values available that may better reflect the toxicological profile of HFPO-DA but a detailed evaluation of the uncertainties associated with these values is outside the scope and objectives of the SLEA. Therefore, the SLEA relies upon the determination from the NC DHHS that, in a regulatory context, the RfDo is protective of human health. Because regulatory risk assessment generally "errs on the side of caution," it must be reiterated that this (or any) RfDo is not predictive of an actual health outcome. The RfDo is described further below.

The USEPA defines an RfDo as "An estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. It can be derived from a [no-observed-adverse-effect level] NOAEL, [low-observed-adverse-effect level] LOAEL, or benchmark dose, with uncertainty factors generally applied to reflect limitations of the data used. Generally used in USEPA's non-cancer health assessments."

To calculate the RfDo, NC DHHS considered seven repeat oral dose studies in rodents of 28 days or longer that were provided by Chemours/DuPont during the USEPA Toxic Substances Control Act (TSCA) review process (NC DHHS, 2018) in derivation of the RfDo. These repeat oral dose studies are preferred to single-dose studies as they are more likely to be applicable to long-term human exposure; however, they are subchronic whereas chronic studies, generally defined as 6 months to a lifetime, are preferred. The NC DHHS consulted with toxicologists and risk assessors at USEPA, the National Institute of Environmental Health Sciences, and the Agency for Toxic Substances and

Disease Registry to identify applicable toxicology information and risk assessment procedures.

The NC DHHS utilized a NOAEL of 0.1 mg/kg-day for liver toxicity endpoints from two subchronic studies in mice (a 28-day study and a reproductive screen) as a point of departure (POD) for calculation of the RfDo. These sub-chronic studies were chosen as the critical studies because they demonstrate adverse effects at the lowest doses tested and associations were evident across multiple studies at the same or similar doses.

The NC DHHS used default uncertainty factors (UFs) recommended by the USEPA to derive their RfDo from the POD. The NC DHHS did not apply a modifying factor (MF) because NOAELs from multiple studies were identical, or within the same order of magnitude, with similar health endpoints (liver toxicity). Additionally, NC DHHS staff concluded that the UFs discussed below adequately addressed the uncertainties of the database. The following default UFs were applied to the POD to derive the RfDo:

- Sub-chronic to chronic uncertainty factor (UF_S): A factor of 10 to account for the uncertainty involved in extrapolating from less than chronic NOAELs to chronic NOAELs;
- Interspecies uncertainty factor (UF_A): A factor of 10 to account for the uncertainty involved in extrapolating from animal data to humans; and,
- Intraspecies uncertainty factor (UF_H): A factor of 10 to account for the variation in sensitivity among the members of the human population

Alternate HFPO-DA RfDo values are available and include a USEPA provisional value and values available from the primary, peer-reviewed literature. Consideration of readily available alternatives and their associated uncertainty are discussed further in Section 8.4.

Additionally, per Paragraph 14 of the Consent Order, Chemours is performing studies to provide both human health and ecological toxicity information for select PFAS, including PFMOAA, PMPA, PFO2HxA, perfluoroethoxypropyl carboxylic acid (PEPA) and Byproduct 2 (PFESA-BP2). These studies are described in the Toxicity Study Workplan (Chemours, 2019) and are anticipated to be completed in 2022.

7.2 Hazard Characterization Methods

There are presently neither federal nor state regulatory standards for HFPO-DA in water, soil, air, or food. As discussed in above, the provisional hazard characterization is predicated on the current RfDo developed by the NC DHHS of 1E-04 mg/kg-day. Using this RfDo, a hazard quotient (HQ) for HFPO-DA was calculated as follows for each receptor-media-EU combination:

$$HQ = ADI \div RfD_o$$

where:

- HQ = Hazard quotient (unitless)
- ADI = Receptor-specific average daily intake of HFPO-DA (mg/kg-day)
- RfDo = Oral reference dose (hazard per mg/kg body weight-day)

Total intake of HFPO-DA was summed across relevant media prior to calculating HQs. An HQ greater than 1 was used as the benchmark for identifying potential human health hazard. Consistent with USEPA Region 4 guidance for conducting human health risk assessments, HQs were rounded to one significant figure (USEPA, 2018d).

7.3 Hazard Characterization Results

Table F-6-1 presents the preliminary hazard characterization for intake of soil, produce, and untreated drinking water at upland EUs 1 through 12. Calculated HQs were less than 1 for the upland receptor exposure scenarios evaluated in the SLEA, indicating potential HFPO-DA exposure is unlikely to pose a hazard to residents, farmers, or gardeners, even in the absence of drinking water treatment. Outside of EU1, the potential hazard from untreated well water consumption accounted for 96% or more of total hazard for each receptor. At EU1, untreated well water consumption accounted for over 99% of the residential intake but only 84% (CTE) to 92% (RME) of the gardener and farmer intake; consumption of homegrown produce accounted for most of the remainder, with soil intake being insignificant.

As stated previously, the use of untreated well water to calculate domestic use substantially overstates the population's potential exposure, as treatment systems provided by Chemours have substantially reduced PFAS in drinking water. Table F-6-1 also presents HQ estimates based on an assumption of 10 ng/L of HFPO-DA in drinking water, which is the maximum concentration in well water that would not require a treatment system. Total HQs for assumed current conditions range from 0.003 to 0.07 and, hence are more than an order of magnitude below unity (1). This indicates that HFPO-DA in soil, produce, and well water in the vicinity of the Facility do not pose a hazard to resident, farmer, or gardener populations under current conditions.

Table F-6-2 presents the preliminary hazard characterization for intake of surface water and fish tissue from the Cape Fear River (10 miles upstream, Facility-adjacent, 4 miles downstream, 8 miles downstream, 55 miles downstream), onsite Pond 1, and offsite Pond B. Calculated HQs were less than 1 for the receptor exposure scenarios evaluated in the SLEA, indicating potential HFPO-DA exposure in the Cape Fear River does not pose a hazard to recreationalist populations. The highest HQs (0.08 to 0.1) are driven by consumption of fish from the downstream EU16 at Bladen Bluffs; otherwise, HQs were less than 0.01, indicating surface water and fish tissue do not pose a hazard to recreationalist populations under current conditions.

Table F-6-3 presents the preliminary hazard characterization for domestic use intakes of Cape Fear River untreated surface water collected from the public supply intake points at Bladen Bluffs (EU16) and Kings Bluffs (EU17). Calculated HQs (0.006 to 0.1) were less than 1 for the receptor exposure scenarios evaluated in the SLEA, indicating potential HFPO-DA exposure in untreated surface water at the Bladen Bluffs and Kings Bluff intake points within the Cape Fear River does not pose a hazard to residential consumers under current conditions.

Table F-7, which is also duplicated as Table 3 for presentation purposes, presents a summary of Total 3+ PFAS and HFPO-DA intake estimates as well as projected HFPO-DA provisional hazard estimates, by EU under CTE and RME conditions. For the RME scenario, calculated intakes and HQs for upland receptors are presented for untreated well water concentrations as well as assumed current conditions; current conditions incorporate an assumption of 10 ng/L HFPO-DA and 70 ng/L total PFAS in untreated groundwater to address the scenario where no drinking water treatment may have been required. Intake and HQ estimates are only presented for the maximum-exposed receptor which is an offsite child gardener, offsite child recreationalist, or offsite child resident. Utilizing the NC DHHS RfDo, individual HQs are less than 1, even in the absence of drinking water treatment, indicating HFPO-DA does not pose a hazard to offsite populations. The conclusion of no hazard for receptors in the upland EUs is further supported by the current conditions HQs which are more than an order of magnitude less than 1 and may be as low as zero.

8 UNCERTAINTY ASSESSMENT

This section discusses uncertainties in the SLEA that may materially impact the understanding of exposure, estimates of intake, and quantitative point estimates of hazard for HFPO-DA. Uncertainties are inherent in the process of quantifying exposure (and hazard) due to the use of environmental sampling results, assumptions regarding receptor behavior, and the quantitative representation of chemical toxicity. Therefore, assumptions used in the HH-SLEA aimed to provide additional conservatism where there was significant uncertainty. Analysis of the critical areas of uncertainty in an assessment provides context for interpreting the quantitative results and better informs risk management decisions.

8.1 Uncertainty in Laboratory Analytical Data

8.1.1 Detection Limits

For groundwater and surface water, the reporting limits (RLs) for Table 3+ PFAS ranged from 2 to 10 ng/L. These concentrations are below the State's provisional health goal for HFPO-DA in drinking water of 140 ng/L[13]. Therefore, the method is sufficiently sensitive for this characterization of HFPO-DA drinking water and recreational direct exposure scenarios.

Methods for analyzing HFPO-DA are sufficiently sensitive to estimate exposures compared to the NC DHHS HFPO-DA RfDo. While the methods are sensitive enough to evaluate exposures compared to the NC DHHS HFPO-DA RfDo, there are presently neither federal nor state regulatory standards for HFPO-DA in water, soil, air, or food. Hence, there is uncertainty with the ability of laboratory analytical limits to detect PFAS at concentrations that may pose a potential human health hazard. The RLs for Table 3+ PFAS ranged from 500 to 550 ng/kg for Method 537 (HFPO-DA only) and 1,000 to 1,200 ng/kg for the Table 3+ Method (20 PFAS). For fish tissue, RLs for Table 3+ PFAS ranged from 1,000 to 1,200 ng/kg. Based on the maximum RL and default child resident and recreational angler exposure assumptions, the estimated PFAS intake from soil and fish fillets would be 1E-08 and 4E-07 mg/kg-day, respectively. These intake estimates are several orders of magnitude below the NC DHHS RfDo of 1E-04 mg/kg-day. Therefore, the HFPO-DA method is sufficiently sensitive based on the NC DHHS HFPO-DA RfDo.

[13] The NC DHHS provisional health goal assumes an individual receives 80% of the acceptable dose (i.e., the RfDo) via other sources, such as food. Hence, the provisional health goal was determined such that intake via drinking water does not exceed 20% of the RfDo. These source contribution estimates are default assumptions and not supported by empirical data. The contribution of HFPO-DA from other sources is likely less than 80% such that concentrations greater than 140 ng/L would also be protective of human health.

Although there is not a current expectation that other Table 3+ PFAS could be orders of magnitude more potent than HFPO-DA, uncertainty associated with RLs remains unresolved pending additional toxicological information.

8.2 Uncertainty in Exposure Point Concentrations

The SLEA was prepared to provide a screening-level evaluation of intake on a regional basis. As such, the EPCs evaluated herein are not representative of a specific exposure point. Rather, they were calculated on an EU-basis and reflect the variability within a given EU. EPC uncertainty is discussed below by environmental contact medium. For all media evaluated herein, the calculated EPCs are considered conservative, i.e., health-protective, relative to future conditions as attenuation of concentrations in all contact media is expected over time based on the implementation of recent and imminent Facility emissions control technologies.

8.2.1 Soil Exposure Point Concentrations

Uncertainty associated with soil EPCs is primarily associated with the use of composite samples to characterize Table 3+ PFAS within each EU. Composite samples inherently represent an average concentration across an EU. Although various composite sampling methods were considered in the development of the SLEA Work Plan, a simplified compositing approach was implemented in the interest of time and access limitations. The sampling deviated from typical ISM sampling most significantly in that replicate samples were not collected. Replicate samples provide information about concentration variability and can be combined to develop upper-bound estimates on the mean to support alternate EPCs. Although the current composite samples reflect an average of conditions throughout a given EU, these results may also be considered *de facto* maximum detected concentrations (in that they are not averaged with replicates). The lack of variability in these data introduces uncertainty to individual intake estimates and it precludes estimation of confidence bounds around an individual's intake.

Although the lack of variability data introduces uncertainty to the SLEA intake estimates, it is unlikely to affect the overall conclusions for the following reasons:

(i) the SLEA demonstrates that incidental soil ingestion accounts for less than 1% of total intake of Table 3+ PFAS, and consumptive use of untreated well water accounts for over 90% of total intake; and,

(ii) PFAS in groundwater and, subsequently, well water are attributed to leaching from soil and there is likely a correlation in concentration between these media such that, for a given receptor, the ratio of intake from these two sources does not significantly vary. Therefore, uncertainty in soil data does not change the

SLEA conclusion that addressing exposure to PFAS via well water consumption meaningfully reduces overall receptor exposure.

Because the EU-specific EPCs in soil constitute a regional approach to characterization, and do not reflect conditions at one location or residence, there was consideration of aggregating data among EU groupings to characterize broader regional influence, based on predominant dispersion and deposition patterns. The individual EU approach to EPC development yields the most conservative estimates of projected intake and hazard. Combination of EUs 1, 5 and 9 to characterize a broader northeast quadrant yielded lower EPCs. Since none of the individual EU-based EPCs resulted in significant projected hazards, no additional effort was expended to evaluate EU grouping.

8.2.2 Produce Exposure Point Concentrations

Empirical produce data were not available. As such, concentrations in homegrown produce were modeled based on uptake from soil, modeled air emissions, and particulate stack emissions deposition rate data.

The soil-derived concentrations are subject to the data and EPC uncertainties described above. Additionally, the assumed root uptake factors may under- or over-estimate produce concentrations. Key input parameters for these uptake factors are the octanol-water partition coefficient (K_{ow}) and the organic carbon-water partition coefficient (K_{oc}). The K_{ow} value used was developed by Chemours using empirical, site-specific data. The K_{oc} values used in the SLEA were derived from the primary literature and may or may not be applicable to study area conditions. In future use of site specific K_{oc} values which Chemours is developing would reduce uncertainty in estimates. The deposition-derived concentrations are uncertain due to the combination of multiple models (e.g., AERMOD, AERMAP, and BPIP), which are each inherently uncertain.

To evaluate the potential magnitude of uncertainty associated with the homegrown produce EPCs, modeled concentrations were compared to concentrations measured in non-edible grasses collected from the upland EUs to support the Ecological Screening Level Exposure Assessment (Geosyntec, 2019f). Use of the plant uptake models indicated that concentrations in produce due to deposition are insignificant relative to root uptake, with modeled concentrations less than 0.001 ng/kg dry weight (based on 2020 emission and flux estimates). Modeled HFPO-DA concentrations due to root uptake ranged from 49.4 to 357 ng/kg dw in aboveground produce and 2,710 to 19,571 ng/kg dw in belowground produce. Concentrations of HFPO-DA measured in non-edible grass ranged from 1,600 to 171,000 ng/kg dw (Geosyntec, 2019f). It is possible that these grasses represent long-lived species (not annuals) and the measured data in biota represent an artifact of pre-air emission control technology conditions, whereas the modeled air data represent the 2020 reduction goals (a two order-of magnitude improvement). A relationship between soil and vegetation could not be reliably established based on the available data.

Given the range of modeled and measured plant concentrations and uncertainty in the relevance of grass concentrations to edible plants, future measured homegrown produce (i.e., fruit and vegetable) concentrations would provide greater certainty in SLEA results.

8.2.3 Drinking Water Exposure Point Concentrations

Over 1,000 wells have been sampled in the vicinity of the Facility and many wells are sampled regularly as part of ongoing monitoring activities. Thus, the drinking water dataset is robust and calculated statistics (i.e., mean, 95 UCL) are likely reliable. Importantly, the EPCs used herein for the drinking water intake assessment and provisional hazard characterization represent untreated well water. As part of the Consent Order implementation, Chemours is required to offer permanent replacement drinking water (in the form of public water or whole building filtration systems) when private wells have HFPO-DA detected above 140 ng/L. When any individual PFAS listed in Consent Order Attachment C, exceeds 10 ng/L or when total PFAS listed in Consent Order Attachment C exceed 70 ng/L, Chemours is required to offer residents up to three under-the-sink reverse osmosis drinking water systems. Chemours offers temporary replacement water supplies (i.e., bottled water) to residents qualifying for a filtration or reverse osmosis system until these systems have been provided. With the implementation of these systems, post-treatment drinking water (where required for qualifying households) shows no detections of any Table 3+ PFS compounds. With the elimination of pre-treatment well water as the source of domestic drinking water supply, associated hazards are expected to substantially decrease. As summarized in Table 4, the provisional HFPO-DA HQs are substantially lower than those calculated based on untreated well water (i.e., based on current conditions, HFPO-DA HQs are expected to decrease from <1 to <0.1).

8.2.4 Surface Water Exposure Point Concentrations

The primary source of uncertainty associated with surface water EPCs is the transient nature of surface water such that the samples evaluated in the SLEA represent a "snap shot" of conditions that may change seasonally or annually. However, inclusion of data collected in different years at different times of the year reduces the likelihood that EPCs were underestimated.

Unlike other media evaluated in this SLEA, the EPCs for surface water were calculated using only detected concentrations. This approach was selected due to the lack of reporting limits for several historical sample results reported by NCDEQ and CFPUA. In general, exclusion of non-detect results is likely to over-estimate rather than under-estimate EPCs such that the SLEA intake and hazard estimates remain conservative.

There is also uncertainty in the total Table 3+ PFAS intake estimates due to inconsistency in target analytes between locations and dates. For example, NCDEQ's analysis of Bladen Bluffs intake samples was limited to HFPO-DA and the CFPUA's analysis of Kings Bluffs intake samples was limited to nine Table 3+ PFAS (including HFPO-DA). As a result, total Table 3+ PFAS intake may be underestimated for the hypothetical residential surface water-as-drinking water scenarios. For other EUs and non-potable use scenarios, the potential for underestimating total Table 3+ PFAS intake is mitigated by the fact that at least one sample at each EU was analyzed for the 20 Table 3+ PFAS. One exception is EU15 where no surface water samples were collected; however, the results of the intake characterization for the upstream and downstream EUs support that concentrations at EU15 are unlikely to pose a hazard.

Overall, given the low magnitude of the intake estimates (relative to untreated well water) and the NC DHHS RfDo, uncertainties identified above are unlikely to affect the SLEA conclusion that surface water is not a significant source of human exposure for Table 3+ PFAS under current conditions.

8.2.5 Fish Tissue Exposure Point Concentrations

The primary source of uncertainty associated with the fish tissue EPCs is the small size of the dataset and the fact that these data represent a "snap shot" of conditions, which may change seasonally or annually.

From a CSM perspective, the fish tissue data were not particularly informative. No concentration gradient was apparent, and the highest tissue concentrations were measured in samples collected farthest from the Facility, approximately 8 miles downstream at Bladen Bluffs. Given this spatial distribution, it is not possible to draw conclusions about concentrations farther downstream. Future additional fish tissue data from further downstream including near Kings Bluff Intake would refine the assessment of the spatial distribution of these compounds in fish.

Due to the limited number of detections in fish fillets a bioconcentration factor for the surface water-to-fish fillet pathway could not be developed. In fish fillets, the most frequently detected Table 3+ PFAS was PFO4DA, which was detected in samples from onsite Pond 1, the Facility-adjacent samples, CFR-09, and Bladen Bluffs, with the highest concentration reported for Bladen Bluffs. Conversely, PFO4DA was reported as non-detect in Bladen Bluffs surface water samples and no relationship between surface water and fish tissue samples was apparent for the other locations where samples were co-located. Based on these data, surface water could not be used as an indicator of fish tissue concentrations and, hence, there is uncertainty associated with the identity of contributing source(s) of PFAS in fish tissue.

8.3 Uncertainty in the Exposure Assessment

The SLEA was prepared to provide a screening-level evaluation of intake and to rank exposure media based on potential for intake of Table 3+ PFAS. Like any regulatory exposure or risk assessment, the exposures evaluated herein are hypothetical in that they do not represent any actual receptor nor are they predictive of health outcomes.

8.3.1 Uncertainty in Exposure Media and Routes

This section discusses the potential effect of including or excluding certain exposure pathways on the results and conclusions of the SLEA.

Subsurface soil intake was not quantitively evaluated in the SLEA. Rather, the SLEA focused on exposure to surface soil (0-0.5 ft bgs) because there is a greater potential for exposure to surface soil and, based on the presumed source of PFAS in soil (i.e., deposition from air), contamination is likely to attenuate with depth. Given the limited number of detections of PFAS in soil, it is not possible to draw reliable conclusions about attenuation with depth. The available data do not exhibit a consistent pattern with respect to leaching potential or attenuation with depth. At EU1 (the EU associated with the highest probability of influence, based on dispersion and deposition patterns), HFPO-DA exhibits an almost order-of-magnitude reduction with depth. PFO2HxA also attenuates significantly, from 2,300 ng/kg in surface soil to non-detect in subsurface soil. At EU3, HFPO-DA attenuates from 360 ng/kg in surface soil to non-detect at depth. At EU4, PFO2HxA attenuates from 1,400 ng/kg in surface soil to ND in subsurface soil. At EUs 4 and 8, HFPO-DA is reported as non-detect in surface soil, with low detections registering with depth. At EU4, PFO2HxA is reported as non-detect in surface soil and 2,300 ng/kg in subsurface soil. Given that exposure to subsurface soil is likely to occur infrequently, if at all, it is reasonable to conclude that the intake of subsurface soil is more than an order of magnitude lower than intake associated with surface soil and further characterization of subsurface soil is not useful for informing risk management decisions. It is also worth noting that collection of soil samples was constrained to available public access roads and rights-of-way. Considering the need for routine roadwork, including regrading, excavation and fill, although attenuation with depth is a reasonable expectation, non-detect results in surface soil extending to detected concentration at depth should not be surprising.

Worker exposure to environmental media was not quantitatively evaluated given that residential exposures are expected to be greater and, as a result, risk management actions to define remedial goals predicated on residential exposure and potential hazard will also be protective of workers. Based on the provisional hazard characterization, HFPO-DA in surface soil, untreated well water, and untreated surface water is unlikely to pose a hazard to offsite workers.

Dermal contact with soil, drinking water, and surface water by relevant receptors was not quantitatively evaluated because no dermal toxicity criteria have been developed at the federal or state level. Exposure studies indicate dermal uptake in animals is undetectable at low doses typical of environmental exposure and human uptake is more than an order of magnitude lower than animal uptake. For human exposures, dermal exposure is expected to be insignificant relative to ingestion exposure. From a relative ranking perspective and based on the chemico-physical properties of PFAS, dermal absorption from water is likely to be greater than that from soil. Hence, inclusion of the dermal pathway would increase the estimated fraction of total intake that is attributable to drinking water. The increase in intake for HFPO-DA could result in provisional HQs for some RME scenarios that exceed 1; however, the marginal increase would not affect the conclusions of this SLEA.

Use of groundwater as irrigation water by farmers and gardeners was not quantitatively evaluated in the SLEA. For this type of use scenario, receptors are primarily exposed to the irrigation water via dermal contact. As discussed above, dermal absorption of PFAS is likely to be insignificant. Irrigation-specific intake is likely to be significantly less than consumption-based intake such that risk management actions to address potable use exposure and potential hazard will also be protective of other groundwater uses. Irrigation water could also represent a source of PFAS to produce. In future empirical produce data would further refine the certainty of exposure estimates.

Consumption of livestock (pork, beef or chicken muscle tissue or poultry eggs) by farmers was not quantitatively evaluated in the SLEA. Likewise, exposures related to recreational hunting activities (e.g., venison, waterfowl) also were not assessed. Existing studies target either secondary ingestion targets (e.g., liver, rather than muscle tissue) or focus on a different class of compounds (e.g., the ‘C8’ compounds, such as perfluorooctanoic acid [PFOA] and perfluorooctane sulfonate [PFOS]). Since these complete exposure pathways are presumed to occur, future assessments that include these lines of evidence are expected to reduce the uncertainty associated with exposure assessment.

Sediment data were not quantitatively evaluated in the SLEA. For human receptors, sediment exposures, if they occur, are primarily associated with recreationalist populations. Generally, sediment exposures can be considered relative to surface soil exposures. While incidental contact (whether ingestion or dermal contact-based) is generally lower than that associated with surface soil, frequency of exposure is more significantly reduced. Residential contact frequency with surface soil is assessed on the basis of 350 days per year spent at the resident's primary address, while sediment contact for a recreational user is assessed on the basis of 12 events per year. With all other parameter values assumed to be equivalent, sediment contact and intake is related to approximately 3% of that associated with soil. As soil represents only 1% of the total intake for of Table 3+ PFAS for a typical resident (and HIs under the RME condition do not exceed one for any receptor in any EU), sediment exposures are presumed to be below a level of significance capable of eliciting an effect on site or risk management decisions.

Based on bioaccumulative potential, sediments are presumed to have a greater impact on fish tissue concentrations and subsequent recreational fish ingestion by humans. Fish tissue concentrations from local ponds and the Cape Fear River represent direct measurements, influenced by dissolved concentrations as well as incidental sediment ingestion by fish. Therefore, the exposure assessment of human consumption of fish inherently accounts for indirect, food chain-related exposures to constituents in sediment. Given the limited potential for direct contact with sediment and the availability of empirical fish tissue data, the lack of sediment data does not present a significant uncertainty in terms of evaluating direct contact human exposures. However, there is uncertainty in how PFAS move through the environment and concentrate in fish tissue, and sediment data may be informative to characterizing this component of the CSM.

8.3.2 Uncertainty in Exposure Assumptions

Media-specific EPCs were varied for the CTE and RME scenarios evaluated herein but the receptor-specific exposure assumptions were held constant. Exposure assumptions generally corresponded to USEPA default recommended RME values used in the development of USEPA's Regional Screening Levels. The conservatism of the RME scenario was compounded by combining RME exposure assumptions with the 95% UCL EPC and is more likely to over-estimate, rather than under-estimate, exposure and hazard. The use of RME exposure assumptions in the CTE scenario also likely over-estimates exposure and hazard, such that none of the combinations used herein represent a "true" CTE scenario (i.e., one that combines average EPCs with average intake estimates). However, from a ranking perspective, the lack of a true CTE scenario is unlikely to have affected the conclusions of the SLEA because for the driving receptor-exposure scenario (i.e., untreated well water consumption), the range of intakes is relatively narrow.

8.4 Uncertainty in the Hazard Characterization

The hazard characterization was specific to HFPO-DA based on the availability of toxicity criteria (i.e., NC DHHS RfDo). Therefore, cumulative hazards may be underestimated but data are not available to evaluate the overall effect, if any, on the conclusions of the hazard characterization. The lack of toxicity data, however, does not affect the conclusion that untreated drinking water represents the most significant source of potential PFAS exposure and exposures related to drinking water are significantly reduced as a function of Chemours-implemented groundwater treatment measures.

The SLEA provisional hazard characterization for HFPO-DA is based on the RfDo of 1E-04 mg/kg-day adopted by the NC DHHS, which is based on liver toxicity endpoints from two subchronic studies in mice. As described below, the use of this value may under or over-estimate potential HFPO-DA.

There is inherent uncertainty in the use of animal toxicity data to characterize potential human health hazards, and this uncertainty is accounted for by the use of UFs used to derive the RfDo. Because many research groups are working in this area, the RfDo could potentially change as new information becomes available that would suggest a different animal model for perfluoroalkyls toxicity or impact the selection of UFs underpinning derivation of the RfDo.

The toxicological database for PFAS continues to expand and others have used the available data to develop alternative toxicity values. A recent study of HFPO-DA (Thompson, et al., 2019) has proposed an additional, provisional RfDo predicated on chronic studies in rats and benchmark dose modeling using deterministic and probabilistic techniques. Thompson et al. derived a deterministic RfDo of 0.02 mg/kg-day and a more conservative probabilistic RfDo of 0.01 mg/kg-day; by both calculation methods, these RfDo values indicate a lower potency than indicated by the 2017 NC DHHS RfDo. Notably, NC DHHS previously developed an RfDo of 0.01 mg/kg-day, also based on a 2-year chronic rat study. The decrease in the NC DHHS RfDo and divergence from the RfDo values developed by Thompson et al. stems from two key differences:

- Study Duration. Thompson et al., 2019 and the 201y6# NC DHHS RfDo were developed from chronic 2-year chronic animal studies whereas the 2017 NC DHHS RfDo was developed from a subchronic, 28-day animal study. Longer-duration animal studies are more relevant to most human exposure and generally given preference when used to develop toxic potency estimates for humans. The need to incorporate an uncertainty factor to address the subchronic basis of the study results in a ten-fold factor lowering of the resultant RfDo.
- Study Species. Thompson et al., 2019 and the 201# NC DHHS RfDo were developed based on liver effects observed in rats whereas the 2017 NC DHHS RfDo was developed from liver effects observed in mice. Hepatocellular hypertrophy and an increased liver-to-body weight ratio are common findings in rodents but are considered non-adverse and less relevant to humans when there is evidence for peroxisome proliferator-activated receptor alpha (PPARα) activation (USEPA, 2018a). It is generally agreed that humans and nonhuman primates are refractory, or at least significantly less responsive than rodents, to PPARα-

mediated effects (Corton et al., 2014; Klaunig et al., 2003; Maloney and Waxman, 1999). Although mice appear to be the more sensitive species to HFPO-DA based on the observed effect levels, the liver lesions in mice are consistent with PPARα activation and, hence, the observed effects are not relevant to humans.

Table 4 presents a comparison of projected RME hazard indices for the maximally-exposed populations for each EU, predicated on use of the NC DHHS and Thompson RfDo values. Table 4 also includes hazards calculated based on the USEPA draft RfDo (developed using methods similar to NC DHHS) that tend to indicate HFPO-DA has a 25% higher potency than the NC DHHS RfDo. It is notable that under each condition, projected hazard indices are equal to or less than 1, indicating no exceedance of available health benchmarks or of USEPA's threshold for identifying a potential human health hazard, even in the absence of drinking water treatment. There is very little difference between the projected hazard estimates predicated on the NC DHHS and USEPA values, with the USEPA RfDo representing a slightly more conservative value resulting in marginal increases of associated hazard. The Thompson study-based RfDo represents a significant change in associated hazard, with a two order-of-magnitude reduction. If viewed as a bounding estimate along with the NC DHHS-based criterion, it provides for a range of potential hazard to support risk management in consideration of the inherent conservatism incorporated into risk characterization methodologies. Of further note, is the fact that these projected hazard indices represent pre-treatment conditions for drinking water or an assumed concentration of 10 ng/L which is the maximum concentration of HFPO-DA that would not require a treatment system. With the imposition of residential treatment systems in the vicinity of the Facility, PFAS concentrations in well water are substantially reduced such that exposure via the drinking water pathway may be as low as zero.

9 CONCLUSIONS

This section summarizes the SLEA and its results, which are tabulated in Table 3.

The objectives of the SLEA were to develop EPCs for Table 3+ PFAS in offsite environmental media, quantify and rank potential intake from these media for assumed receptor populations, and provide a provisional estimate of potential human health hazard.

Based on the existing CSM and to characterize the regional distribution of PFAS in the vicinity of the Facility, the study area was evaluated on an EU-basis, consisting of 12 upland EUs, five Cape Fear River EUs, one onsite pond EU, and one offsite pond EU. The nature and extent of Table 3+ PFAS in the vicinity of the Facility were characterized using air emission rates, soil, untreated well water, untreated surface water, and fish tissue data collected between 2017 and 2019. Additionally, a current conditions drinking water scenario was evaluated based on the treatment requirements of the Consent Order. Based on current use conditions, the SLEA identifies residents, farmers, and gardeners as exposure populations for the upland EUs; recreationalists as exposure populations for the Cape Fear River and ponds; and residential potable water users as exposure populations for untreated surface water from the Cape Fear River collected at public supply intake points (i.e., Bladen and Kings Bluffs). Potential intake was calculated using RME exposure assumptions and a range of EPCs for each environmental/contact medium. Based on available toxicity data, the intake characterization focuses on ingestion pathways. Although the SLEA focuses on potentially complete exposure pathways, it is important to note that the exposure assumptions do not represent an actual receptor; in reality, some (or all) of these assumed exposure pathways may be incomplete for an actual receptor.

The SLEA identifies untreated well water as the primary source of potential PFAS intake, and hence, exposure. However, even in the absence of treatment, no hazard was identified for offsite resident, gardener, and farmer populations exposed to soil, well water, and produce in the vicinity of the Facility. For residents, intake of PFAS from direct exposure to soil was insignificant relative to the RfDo and in comparison to domestic use of well water. Residential intake of PFAS from untreated well water accounted for greater than 96% of the total intake and was two or more orders of magnitude greater than intake from soil. For gardeners and farmers, the contribution from soil was also insignificant relative to consumption of untreated well water; however, due to a lack of empirical produce data, there is uncertainty in the total intake estimates for farmers and gardeners and in the relative contributions from homegrown produce and untreated drinking water. The modeled produce concentrations and measured non-edible grass concentrations provide a preliminary indication that produce consumption is unlikely to pose a hazard under current conditions and, due to Facility air emissions reductions, the potential for exposure will further decrease in the future. Finally, regardless of the contribution of homegrown produce to potential intake, replacement drinking water and drinking water filtration systems reduces overall exposures and potential hazard to upland receptors.

The SLEA indicated that recreational exposure to surface water and recreational fish consumption is unlikely to be a significant source of PFAS intake and, based on the provisional hazard characterization, HFPO-DA does not pose a human health hazard. The relative contribution of surface water and fish consumption to recreationalists' total intake estimates varied between EUs; no concentration gradient was apparent based on the fish fillet data, no species-specific relationships were apparent, and no correlation to surface water concentration was apparent. Hence, there is uncertainty associated with the bioconcentration mechanisms for fish. It is also notable that the maximum detected PFAS fish tissue concentrations were measured in fish fillet samples collected from the sample point farthest downstream from the Facility (i.e., Bladen Bluffs), indicating there is uncertainty with respect to the spatial distribution of PFAS in the Cape Fear River and impact on fish fillet data.

Under current conditions, no human health hazards from HFPO-DA were identified for consumptive use of untreated surface water from the Bladen and Kings Bluffs public supply intake points.

In summary, the SLEA demonstrates that current concentrations of HFPO-DA in the environment in the vicinity of the Facility are unlikely to pose a hazard to human health, even in the absence of groundwater treatment. The Chemours-provided drinking water treatment systems have effectively reduced Table 3+ PFAS concentrations in residential wells (i.e., the primary source of potential PFAS intake) such that in the vicinity of the Facility, the population's potential for Table 3+ PFAS exposure via domestic water has substantially decreased. Due to Facility air emissions reductions, the potential for exposure to PFAS in environment media will continue to decrease over time.

Notes:

[1] This summary table presents the calculated intakes and HQs for the most sensitive receptor for a given EU scenario.

[2] Intake estimates for EU1 through EU12 were calculated using (1) untreated well water data collected between 2017 and 2019 and (2) based on presumed maximum concentrations under current conditions, which correspond to 70 ng/L for total PFAS and 10 ng/L for HFPO-DA. Hazard estimates for EU1 through EU12 were calculated using (1) untreated well water data collected between 2017 and 2019 and (2) based on a presumed maximum concentration of 10 ng/L for HFPO-DA.

[3] Only HFPO-DA data were available for surface water intake exposure points.

Abbreviations:

"--" - not available/not calculated
n/a - not applicable
CFR - Cape Fear River
CTE - central tendency exposure
EU - Exposure Unit
HFPO-DA - Hexafluoropropylene oxide dimer acid
HQ - hazard quotient
mg/kg-day - milligram(s) of constituent intake per kilogram of body weight per day
ND - constituent not detected
RfDo - non-cancer oral reference dose
RME - reasonable maximum exposure
SW - surface water
NC DHHS - North Carolina Department of Health and Human Services

TABLE 4
SUPPLEMENTAL HAZARD CHARACTERIZATION BASED ON ALTERNATIVE RfD VALUES

Notes:
[1] This summary table presents the calculated intakes and HQs for the most sensitive receptor for a given EU scenario.
[2] Intake estimates include HFPO-DA from the following sources: EU1 through EU12 - soil, homegrown produce, and drinking water; EU13 through EU19 - surface water and fish tissue; and EU16 and 17 (Intake Point) - surface water as drinking water.
[3] Intake and hazard estimates based on untreated well water data collected between 2017 and 2019.
[4] Current conditions intake and hazard estimates are based on assumed drinking water concentrations of 10 ng/L for HFPO-DA (see Section 7 of the Human Health SLEA Report).
[5] HQs are calculated for a range of RfDo values, which are discussed as part of the SLEA uncertainty assessment.

Notes:

[1] The SLEA is specific to offsite receptors.
[2] Subsurface soil was qualitatively evaluated in the SLEA.
[3] Dermal exposure pathways were qualitatively evaluated in the SLEA.
[4] Soil particulates and vapors in ambient air are not evaluated in the SLEA as this pathway is unlikely to be significant.
[5] Produce concentrations were estimated from soil data and modeled deposition rate data.
[6] Sediment data were qualitatively evaluated in the SLEA.
[7] Intake points for domestic water are located at Bladen and Kings Bluffs. Untreated data were used in the SLEA as a conservative estimate of potential intake.

Complete exposure pathway quantitatively evaluated in the SLEA.
Potentially complete pathway with limited potential for intake that is qualitatively evaluated in the SLEA.
Potentially complete pathway evaluated using a higher-exposure receptor, where:

- Worker exposure to soil and drinking water was excluded from quantitative evaluation on the basis that risk management based on residents will be protective of the receptor group.
- Recreationalist exposure to soil was excluded from quantitative evaluation on the basis that risk management based on residents will be protective of the receptor group.
- Resident, farmer, and gardener fish consumption was excluded from quantitative evaluation on the basis that risk management based on recreationalists will be protective of these receptor groups.

Incomplete or insignificant exposure pathway; no evaluation or management action is necessary.

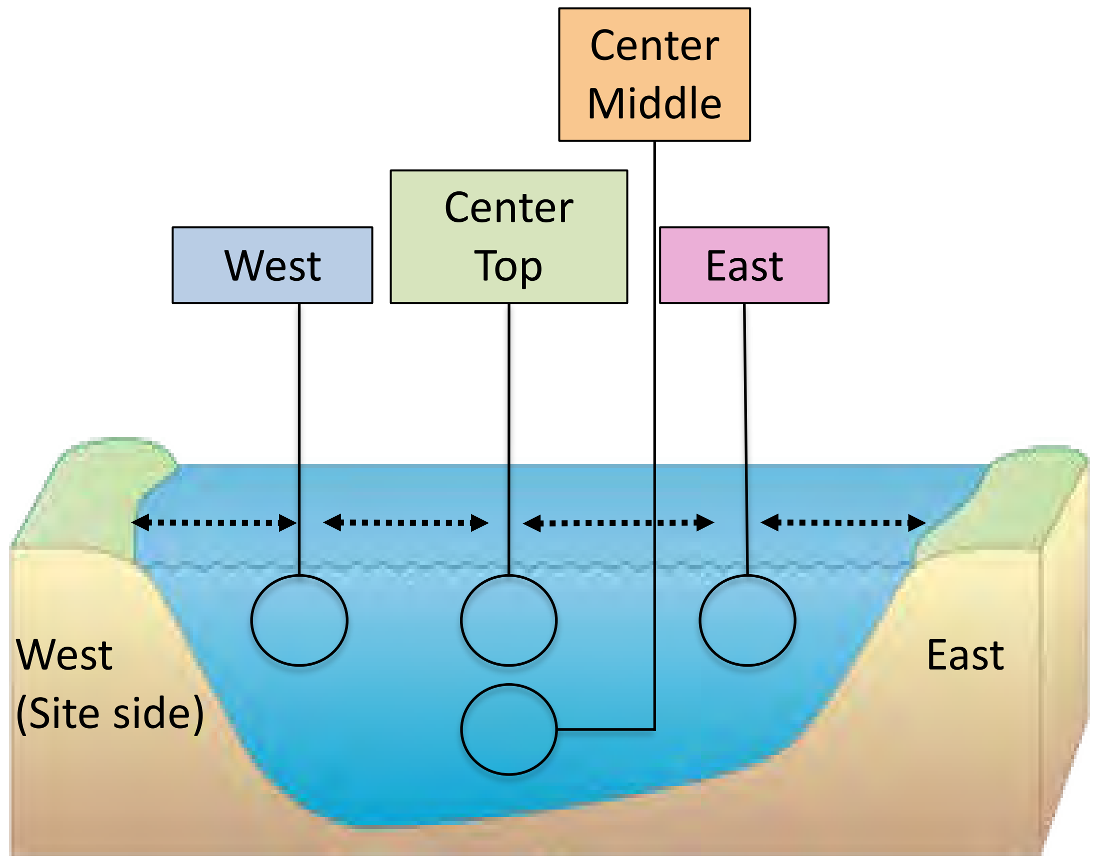
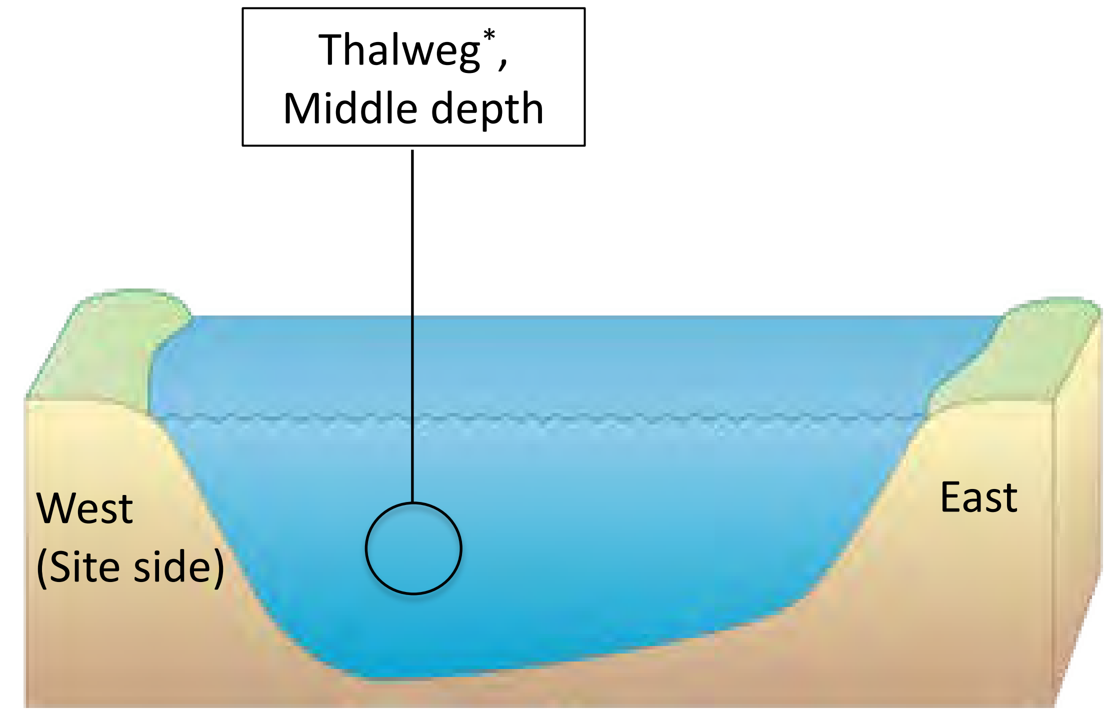
2017-2018 Local Program and 2019 SLEA Surface Water Sampling



◄········► 25 % of river width

Sampling Location Selection Rationale:
Assess how concentrations differ across cross-section, particularly close to Site

2018 Regional Program, 2018 Post-Florence, and Spring 2019 Surface Water Sampling



*Thalweg: Deepest part of the channel cross section

Sampling Location Selection Rationale:
Assess how concentrations vary along the length of the river. The majority of flow occurs at the thalweg, which is typically the most mixed part of river and expected to be representative of average concentrations.

APPENDIX A
Consent Order

STATE OF NORTH CAROLINA

COUNTY OF BLADEN

IN THE GENERAL COURT OF JUSTICE
SUPERIOR COURT DIVISION
17 CVS 580

STATE OF NORTH CAROLINA, *ex rel.*, MICHAEL S. REGAN, SECRETARY, NORTH CAROLINA DEPARTMENT OF ENVIRONMENTAL QUALITY,

Plaintiff,

CAPE FEAR RIVER WATCH,

Plaintiff-Intervenor,

v.

THE CHEMOURS COMPANY FC, LLC,

Defendant.

CONSENT ORDER

WHEREAS, since July 1, 2015, Defendant The Chemours Company FC, LLC ("Chemours") has owned and operated a chemical manufacturing facility called the Fayetteville Works ("Facility") in Bladen County, North Carolina, which, prior to July 1, 2015, was owned and operated by E. I. DuPont de Nemours & Company, Inc. ("DuPont").

WHEREAS, on September 7, 2017, Plaintiff, the State of North Carolina, by and through Michael S. Regan, Secretary of the North Carolina Department of Environmental Quality ("DEQ"), filed a Complaint and motion for a temporary restraining order in this Court against Chemours, seeking various forms of relief relating to alleged violations by Chemours and DuPont of North Carolina water quality laws and regulations arising out of the discharge of certain per- and polyfluoroalkyl substances ("PFAS"), including a compound often referred to by the trade name "GenX," into surface water and groundwater;

WHEREAS, on September 8, 2017, the Court entered a partial consent order resolving DEQ's motion for a temporary restraining order;

WHEREAS, on April 10, 2018, Plaintiff filed an Amended Complaint against Chemours that, among other things, sought further relief, including relating to alleged violations by Chemours and DuPont of North Carolina water quality laws and regulations arising out of the discharge or release of per- and polyfluoroalkyl substances into surface water, groundwater and the air;

WHEREAS, on July 11, 2018, Chemours filed an Answer to the Amended Complaint denying the allegations that Chemours had violated State laws or regulations and setting forth multiple affirmative defenses to Plaintiff's claims;

WHEREAS, DEQ has issued Notices of Violation to Chemours dated September 6, 2017, November 13, 2017, February 12, 2018, and June 1, 2018 (collectively, "the NOVs"), relating to the alleged violations set forth in the Complaint and/or Amended Complaint, and Chemours responded to the NOVs;

WHEREAS, since the filing of the Complaint, the Parties have conducted good-faith discussions to develop comprehensive and effective solutions to the environmental concerns that have been raised concerning the Facility's operations, including those underlying the allegations of the Amended Complaint and the NOVs;

WHEREAS, the Parties have negotiated this Consent Order that the Parties believe will provide such solutions;

WHEREAS, pursuant to this Consent Order, and in consideration of the release of claims and the other relief set forth herein, Chemours will, among other things:

(i) install abatement technology at the Facility (including a thermal oxidizer) that, once fully operational, will permanently reduce annual air emissions of GenX Compounds and other PFAS (as those terms are defined below) by at least 99% from baseline levels and control all PFAS emissions from process streams routed to the thermal oxidizer at an efficiency of 99.99%;

(ii) on an interim basis, reduce annual air emissions of GenX Compounds (as defined below) by at least 82% beginning as of October 6, 2018 and by at least 92% beginning as of December 31, 2018;

(iii) continue to capture for off-site disposal all process wastewater from its operations at the Facility unless or until an NPDES Permit is issued authorizing the discharge of process wastewater;

(iv) undertake the measures specified below with respect to abatement and remediation of groundwater contamination and provision of alternative drinking water supplies; and

(v) agree to the measures specified below to verify and ensure compliance with the foregoing commitments and the requirements of this Consent Order;

WHEREAS, Chemours denies any violation of any law, regulation or permit, including the claims of any such violation made in the Amended Complaint or the NOVs, and has agreed to this Consent Order solely to avoid the expense, burden and uncertainty of litigation and to address community concerns about the Facility;

WHEREAS, Chemours and DEQ have consented to the intervention of Cape Fear River Watch in this matter for the purpose of entering into this Consent Order and resolving Cape Fear River Watch's pending actions in Cape Fear River Watch v. North Carolina Department of Environmental Quality, 18 CVS 2462 (New Hanover Cty. Sup. Ct.) and Cape Fear River Watch v. Chemours Company FC, LLC, No. 7:18-cv-00159 (E.D.N.C.);

NOW THEREFORE, the parties agree, and the Court orders, as follows:

A. DEFINITIONS

"**Amended Complaint**" means the amended complaint filed by the Plaintiff in this matter on April 10, 2018.

"**Complaint**" means the complaint filed by the Plaintiff in this matter on September 7, 2018.

"Defendant" or **"Chemours"** means The Chemours Company FC, LLC, a Delaware limited liability company registered and doing business in North Carolina.

"**DEQ**" means the North Carolina Department of Environmental Quality, including all its divisions.

"DAQ" means the North Carolina Division of Air Quality, a division of DEQ.

"DWM" means the North Carolina Division of Waste Management, a division of DEQ.

"DWR" means the North Carolina Division of Water Resources, a division of DEQ.

"Facility" means Chemours' Fayetteville Works Facility located at 22828 NC Highway 87 W, Fayetteville, Bladen County, North Carolina, which Facility is owned by, and operated in part by, Chemours.

"GenX" means the chemical C3 Dimer Acid (also known as HFPO Dimer Acid), which has a CAS number of 13252-13-6.

"GenX Compounds" means C3 Dimer Acid (also known as HFPO Dimer Acid), CAS No. 13252-13-6, C3 Dimer Acid Fluoride (also known as HFPO Dimer Acid Fluoride), CAS No. 2062-98-8, and C3 Dimer Acid Ammonium Salt (also known as HFPO Dimer Acid Ammonium Salt), CAS No. 62037-80-3.

"NOVs" means the Notices of Violation issued by DEQ to Chemours dated September 6, 2017, November 13, 2017, February 12, 2018, and June 1, 2018. "NOVs" also includes the anticipated notice of violation for the truck spill that occurred during Hurricane Florence on September 18, 2018.

"PFAS" means perfluoroalkyl and polyfluoroalkyl substances.

"Plaintiff" means the sovereign State of North Carolina on behalf of DEQ.

"2017 Total Reported Emissions" means total facility-wide estimated emissions of GenX Compounds in the amount of 2302.7 lbs as reported by Chemours to DAQ in Chemours' Letter of April 27, 2018 and the document, "HFPO-DA Baseline Emission Estimates," attached thereto as Exhibit 2.

B. JURISDICTION AND VENUE

1. Plaintiff is the sovereign State of North Carolina. This action was brought on the relation of Michael S. Regan, Secretary of DEQ, the State agency established pursuant to N.C. Gen. Stat. § 143B-279.1 *et seq.*, and vested with the statutory authority to enforce the State's

environmental protection laws, including laws enacted to protect the water and air quality of the State.

2. Plaintiff-Intervenor Cape Fear River Watch is a § 501(c)(3) nonprofit public interest organization headquartered in Wilmington, North Carolina that engages residents of the Cape Fear watershed through programs to preserve and safeguard the river. The organization has 1,100 members, including members who live near, drink water from, and fish, swim, and boat on the Cape Fear River downstream of Chemours' Fayetteville Works Facility. Cape Fear River Watch's mission is "to protect and improve the water quality of the Lower Cape Fear River Basin through education, advocacy and action."

3. Defendant Chemours is a Delaware limited liability company registered and doing business in North Carolina. Chemours owns the Fayetteville Works facility located at 22828 NC Highway 87 W, Fayetteville, Bladen County, North Carolina and operates a portion of that facility.

4. This Court has jurisdiction pursuant to N.C. Gen. Stat. § 143-215.6C, N.C. Gen. Stat. § 143-114C, N.C. Gen. Stat. § 7A-245(a)(2) and N.C. Gen. Stat. § 1-493.

5. Bladen County, North Carolina is a proper venue because portions of the Fayetteville Works facility are located in Bladen County and the Amended Complaint alleges violations occurring in Bladen County. N.C. Gen. Stat. § 143-215.6C; N.C. Gen. Stat. § 143-114C.

6. The Honorable Douglas B. Sasser, Senior Resident Superior Court Judge, presides over this matter by designation pursuant to Rule 2.1 of the General Rules of Practice.

C. COMPLIANCE MEASURES – AIR EMISSIONS

7. Control Technology Improvements:

a. *Second Phase Scrubber.* Chemours completed installation of a packed bed scrubber ("Second Phase Scrubber") to control emissions from the Division Waste Gas Scrubber on November 7, 2018.

b. *Vinyl Ethers North Carbon Adsorber Project*: Chemours has made improvements to allow for the control of emissions from the Second Phase Scrubber by the Vinyl Ethers North Carbon Adsorber Unit ("Vinyl Ethers North Carbon Adsorber Project") in accordance with the following schedule and conditions:

i. On October 19, 2018, Chemours submitted to DAQ a process hazard assessment pertaining to the Vinyl Ethers North Carbon Adsorber Project.

ii. On December 26, 2018, Chemours completed construction of the Vinyl Ethers North Carbon Adsorber Project. All emissions from the Second Phase Scrubber are controlled by the Vinyl Ethers North Carbon Adsorber Unit subject to such unit downtime as may be required by the process hazard assessment or as necessary for maintenance of the unit. Chemours will use its best efforts consistent with safe operations to minimize unit downtime.

iii. Within ninety (90) days of installation, Chemours shall submit a report to DAQ demonstrating that the Vinyl Ethers North Carbon Adsorber

Unit operates with a minimum control efficiency of 93% for GenX Compounds.

c. *Thermal Oxidizer*. By December 31, 2019, Chemours shall install a thermal oxidizer to control all PFAS in process streams from the HFPO Process, the Vinyl Ethers North Process, the Vinyl Ethers South Process, the RSU Process, the TFE Process, the MMF Process, and the Polymers Process. Within ninety (90) days of installation, Chemours shall demonstrate that the thermal oxidizer controls all PFAS at an efficiency of 99.99%.

8. GenX Emissions Reduction Milestones: Chemours shall achieve the overall emissions reductions of GenX Compounds in accordance with the following schedule.

a. By October 6, 2018 and for the twelve-month period beginning on that date, Chemours shall reduce Facility-wide air emissions of GenX Compounds on an annualized basis by at least 82% from 2017 Total Reported Emissions. To demonstrate compliance with this paragraph, Chemours shall follow the procedure in paragraph (b) below, except the demonstration year shall run from October 6, 2018 through October 5, 2019 (rather than Calendar Year 2019) and the final report demonstrating compliance shall be due on or before December 5, 2019 (rather than February 28, 2020).

b. By December 31, 2018 and for the twelve-month period beginning on that date, Chemours shall reduce Facility-wide air emissions of GenX Compounds on an annualized basis by at least 92% from 2017 Total Reported Emissions. To demonstrate compliance with this paragraph, Chemours shall:

i. Conduct emissions testing for GenX Compounds emissions sources to determine GenX Compounds emission rates for each product campaign. Emissions testing shall be conducted during the first campaign of that product of the Calendar Year 2019. Control device operating parameters must be recorded during the testing. Emissions test reports shall be submitted to DAQ within forty-five days of completion of the emissions test; and

ii. Submit a report demonstrating compliance to DAQ by February 28, 2020. This report shall include GenX Compounds emissions in pounds per year based on test data or established emission factors where test data are not available, hours of operation for each campaign, and production data. The report shall quantify any other emissions including but not limited to fugitive, maintenance, malfunction and accidental emissions. The report shall also include a summary of control device operating parameters throughout the year.

c. By December 31, 2019 and for each consecutive twelve-month period following that date, Chemours shall reduce Facility-wide annual air emissions of GenX Compounds by at least 99% from 2017 Total Reported Emissions. To demonstrate compliance with this paragraph, Chemours shall:

i. Conduct emissions testing for the thermal oxidizer to determine the emissions rate of GenX Compounds. Emissions testing shall be completed by March 31, 2020. Emissions test reports shall be submitted to DAQ within forty-five days of completion of the emissions test; and

ii. Submit a report demonstrating compliance to DAQ by February 28, 2021. This report shall include GenX Compounds emissions in pounds per year based on test data, or established emission factors where test data are not available, hours of operation, and production data. The report shall quantify any other emissions including but not limited to fugitive, maintenance, malfunction and accidental emissions. The report shall also include a summary of control device operating parameters throughout the year.

iii. Chemours shall repeat this compliance demonstration for each subsequent calendar year unless and until DAQ issues a modified Air Quality Permit to Chemours, incorporating a 99% or greater reduction requirement.

d. To provide ongoing assurance of compliance with the interim emissions reductions required under subparagraphs (a) and (b), Chemours shall submit an inventory of emissions of GenX Compounds from all sources on a monthly basis within 21 days of the end of each month. This inventory shall include (1) a detailed summary of emissions during the previous calendar month; (2) cumulative emissions to date during the relevant annual compliance period; and

(3) projected emissions during the relevant annual compliance period.

9. Disclosure of PFAS emissions: Chemours shall have an ongoing duty to disclose to DAQ (i) any identified previously undisclosed PFAS and emissions rates for those PFAS, and (ii) any new process or production that may lead to the addition of any previously undisclosed PFAS in the Facility's air emissions. For any such PFAS, Chemours shall provide DAQ with any available analytical test methods and lab standards. Chemours shall provide DAQ with all known test methods and lab standards for PFAS in air emissions at the facility by December 31, 2018.

D. COMPLIANCE MEASURES – SURFACE WATER

10. No Discharge of Process Wastewater from Chemours' Manufacturing Areas: Chemours shall not discharge process wastewater from Chemours' manufacturing areas until issuance of an NPDES Permit issued under N.C. Gen. Stat. § 143-215.1 and 15A NCAC 2B ("NPDES Permit") expressly authorizing the discharge of such process wastewater and with such limits as DEQ reasonably deems necessary and appropriate to control the discharge of GenX Compounds and other PFAS. In accordance with applicable law, in setting such limits, DEQ shall take into account available health information including any information produced pursuant to this Consent Order.

11. Characterization of PFAS in Process and Non-process Wastewater and Stormwater at the Facility:

a. *Test methods and lab standards*: By January 31, 2019, Chemours shall (a) provide DWR with all known analytical test methods and lab standards for all PFAS in all process and non-process wastewater and stormwater at the Facility, including but not limited to all process and non-process wastewater and stormwater discharged through Outfall 002, and (b) submit a plan and schedule for conducting non-targeted analysis of all process and non-process wastewater and stormwater streams to identify any additional PFAS and developing test methods and lab standards for such compounds. Chemours shall commence implementation of such plan within thirty (30) days of approval by DEQ. Chemours shall follow the EPA's Protocol for Review and Validation of New Methods for Regulated Organic and Inorganic Analytes in Wastewater under EPA's Alternate Test Procedure Program, *see* https://www.epa.gov/sites/production/files/2016-03/documents/chemical-new-method-protocol_feb-2016.pdf, and shall write each test procedure in the standard EPA format.

b. *Sampling plan*: By December 31, 2018, Chemours shall submit a sampling plan to DWR for approval. This sampling plan shall include proposed locations for the sampling to carry out the initial characterization of all PFAS described in subparagraph (c).

c. *Initial characterization*: Within thirty (30) days of approval of the sampling plan, Chemours shall commence submission of quarterly reports to DEQ identifying PFAS constituents and initial concentrations at any level above the practical quantitation limit in all process and non-process wastewater and stormwater at the Facility, including, but not limited to, all process and non-process wastewater and stormwater discharged through Outfall 002. As part of these reports, process and non-process wastewater and stormwater shall be characterized from each of Chemours' manufacturing areas as well as from the manufacturing areas of Chemours' tenants, Kuraray and DuPont. Similar testing for PFAS constituents in the raw water intake shall be performed in conjunction with other sampling in order to assess background concentrations. The final quarterly report shall be submitted, and initial characterization of all PFAS completed, no later than eighteen (18) months after approval of the sampling plan.

d. *Ongoing sampling*: For all PFAS for which test methods and lab standards have been developed Chemours, at least every two months, shall sample for each such PFAS at approved locations and report the results to DWR. Approved locations shall, at a minimum, include the locations described in subparagraph 11(c), unless Chemours has demonstrated through its initial characterization that a manufacturing area does not contribute to PFAS loading. After two years of such sampling, Chemours may request that DWR agree to a reduced sampling frequency.

e. *Ongoing duty to disclose*: Chemours shall have an ongoing duty to disclose (i) any previously undisclosed PFAS and concentrations of any previously undisclosed PFAS in all process and non-process wastewater and stormwater at the Facility, and (ii) any new process or production that may lead to the addition of any previously undisclosed PFAS in process and non-process wastewater and stormwater at the Facility. For any such PFAS, Chemours shall provide DWR with available test methods and lab standards as specified in subparagraph (a) above.

11.1 Characterization of PFAS Contamination in Downstream Raw Water Intakes: Within six months of entry of this Order, Chemours shall submit an analysis to DEQ reporting contributions of PFAS (including identification and mass loading of each PFAS) from the Facility to the raw water intakes of downstream public water utilities.

11.2 Characterization of PFAS Contamination in River Sediment: Within six months of entry of this Order, Chemours shall develop a plan for assessing the nature and extent of PFAS sediment contamination in the Cape Fear River originating from the Facility, and submit the plan and a schedule for implementation to DWR for approval. Within thirty (30) days of DEQ's approval of the plan and schedule by DWR, Chemours shall commence implementation of the plan. Upon completion, Chemours shall summarize its findings in a report to be submitted to DEQ, Cape Fear River Watch, and to downstream water utilities.

12. Accelerated Reduction of PFAS Contamination in the Cape Fear River and Downstream Water Intakes:

a. In order to reduce PFAS contamination in the Cape Fear River and in the raw water intakes of downstream public water utilities on an accelerated basis, within six months of entry of this Order, Chemours shall submit to DEQ and Cape Fear River Watch a plan demonstrating the maximum reductions in PFAS loading from the Facility (including loading from contaminated stormwater, non-process wastewater, and groundwater) to surface waters, including Old Outfall 002, that are economically and technologically feasible, and can be achieved within a two-year period ("PFAS reduction targets"). The plan shall be supported by interim benchmarks to ensure continuous progress in reduction of PFAS loading. If significantly greater reductions can be achieved in a longer implementation period, Chemours may propose, in addition, an implementation period of up to five years supported by interim benchmarks to ensure continuous progress in reduction of PFAS loading. In demonstrating maximum reductions in PFAS loading to the Cape Fear River, Chemours may take into account the PFAS loading reductions to be achieved pursuant to subparagraph 12(e). Subject to approval by DEQ, the plan may include actions to be undertaken by other entities that have contributed to the need for such remediation. Chemours shall simultaneously transmit the plan to downstream public water utilities. DEQ will make DEQ staff available to meet with downstream public water utilities to receive input on the plan.

b. The plan shall include a model accounting for all sources of PFAS (including identification and mass loading of all PFAS) from the Facility contributing to the loading of PFAS into the Cape Fear River, Willis Creek, Georgia Branch, and Old Outfall 002.

c. The model shall be prepared by a third party approved by DEQ after consultation with Cape Fear River Watch. Prior to conducting the modeling analysis, the third party shall submit to DEQ for approval a scope of work describing the modeling analysis. DEQ shall consider all timely comments received from Cape Fear River Watch prior to agency approval of any such document.

d. DEQ and Cape Fear River Watch shall review the plan developed by Chemours, and the Parties shall work together in good faith to determine if the PFAS reduction targets identified by Chemours represent the maximum reductions that are economically and technologically feasible, and can be implemented over a two-year period (or longer as proposed in an alternate plan), or whether the Parties can identify and agree upon further reductions. The burden is on Chemours to demonstrate that the concentrations of GenX and perfluoro-1-methoxyacetic acid (PFMOAA) detected in Outfall 002 cannot be reduced by at least 80% from baseline levels, including after measurable storm events, as defined in 40 C.F.R. 122.21(g)(7)(ii), within 2 years.

e. By September 30, 2019, Chemours shall complete, at a minimum, monthly surface water sampling in Old Outfall 002 (beginning no later than March 2019) at the locations marked A (mouth of stream), A (seep), B, C, D, E, Option B (proposed dam), and Creek A2 in **Attachment A** for any PFAS for which test methods and laboratory standards have been developed as of the date of entry of the Consent Order. Also by September 30, 2019, Chemours shall complete pilot scale testing of treatment equipment to determine its control efficiency for all PFAS identified in Old Outfall 002. The results of this pilot testing shall be supported by at least three (3) months of sampling data, and submitted to DWR for review and approval. In addition, within ninety (90) days of entry of this Consent Order, Chemours shall submit a plan analyzing the options below and implement one of them upon approval by DEQ and Cape Fear River Watch:

i. Provided that DEQ issues any necessary permits authorizing such discharge and subject to any conditions imposed by such permits, and provided that any other permitting authority with jurisdiction over the project issues any other necessary permits, by September 30, 2020, at or near the Option B location (proposed dam) depicted in **Attachment A**, Chemours shall implement a system to capture the dry weather flow at that location and treat such water prior to discharge pursuant to such permits or authorizations as DEQ may issue. Chemours shall submit timely and complete applications and take all other actions necessary to obtain any necessary permits or authorizations to carry out the requirements of this paragraph. The treatment system shall meet such discharge standards as shall be set by DEQ, and shall, in addition and at a minimum, be at least 99% effective in controlling indicator parameters, GenX and PFMOAA;

ii. By September 30, 2020, Chemours shall implement such measures to reduce PFAS loading from Old Outfall 002 to the Cape Fear River that will achieve results that are demonstrated to be equivalent to or greater than the reductions that would be obtained under subparagraph (i) above.

Following the completion of the groundwater remediation set forth in Paragraph 16, Chemours shall remove any dam(s) placed within Old Outfall 002 and restore the channel to its condition prior to the installation of the dam.

f. Provided that the Parties come to an agreement regarding additional PFAS reductions, within eight months after entry of this Order, DEQ, Cape Fear River Watch and Chemours shall jointly move to amend this Consent Order to incorporate any agreed upon reductions as enforceable requirements of this Consent Order as well as stipulated penalties for non-compliance. If DEQ, Cape Fear River Watch, and Chemours are unable to mutually agree upon additional PFAS reductions within eight months after entry of this Order: (i) the Parties may jointly stipulate to additional time in which to submit a joint motion to amend, or (ii) Cape Fear River Watch, DEQ, and Chemours may bring any dispute regarding the additional reductions before the Court for resolution. In resolving any such dispute, the Court shall, in addition to considering testimony by qualified experts presented by the parties, give due regard to the demonstrated knowledge and expertise of DEQ with respect to the evaluation of the economic and technological feasibility of environmental remediation and the application of that knowledge and expertise to other remediation projects. After the Court amends this Consent Order or otherwise resolves this issue, Chemours shall commence implementation within thirty days of such an amendment or other resolution of the issue, and comply with the reduction targets mandated.

g. Nothing in this paragraph shall be construed to limit Chemours' obligations to submit and implement a complete Corrective Action Plan pursuant to paragraph 16, but Chemours may propose such a Corrective Action Plan that integrates the requirements of this paragraph.

13. Facility Site Visit: By February 28, 2019, Chemours shall provide DEQ and Cape Fear River Watch with a tour of the exterior grounds of the Facility, including Old Outfall 002, Outfall 002, the terracotta pipe (which formerly carried industrial process wastewater), discharge locations to surface waters, and the proposed sampling locations contemplated by paragraph 11(b).

14. Toxicity Studies: Within thirty (30) days of entry of this Consent Order, Chemours shall submit a plan and proposed schedule for review and approval by DEQ for funding and facilitating the conducting of an initial set of toxicity studies by a qualified third party approved by DEQ relating to both toxicity assays informative to human health and aquatic life sufficient to aid in development of surface water and groundwater regulatory standards for up to five PFAS as determined by DEQ. The plan shall provide for the studies and parameters identified in **Attachment B** as well as technologically feasible dosing parameters to be agreed upon by

Chemours and DEQ. Chemours shall implement the measures set forth in the approved plan. DEQ reserves the right to seek additional toxicity studies or additional health, chemical persistence and environmental fate information beyond the scope of the initial set of studies required by this paragraph. DEQ shall consider public comments in determining what additional toxicity studies or additional health, chemical persistence and environmental fate information are needed. Chemours reserves the right to contest any efforts by DEQ to seek additional toxicity studies or additional health, chemical persistence and environmental fate information from Chemours beyond the scope of the initial set of studies required by this paragraph. Additionally, modification of toxicity study(ies) specified in Attachment B shall permitted, upon agreement between DEQ and Chemours, only if DEQ determines that such modification will provide substantially better information. Any dispute with respect to this paragraph that the parties are unable to resolve after good faith negotiations shall be resolved by the Court, which shall determine whether the disputed activity is reasonably necessary to achieve the objectives of this paragraph.

15. Notice to and Coordination With Water Utilities: In the event of an upset or other operating condition at the Facility that has the potential to cause (i) a discharge of GenX Compounds or any PFAS for which analytical test methods and lab standards have been developed into the Cape Fear River through Outfall 002 at concentrations exceeding 140 ng/L, or any applicable health advisory, whichever is lower, or (ii) a material increase in the concentration of any PFAS in effluent being discharged into the Cape Fear River through Outfall 002 or any future permitted discharge, Chemours shall provide notice to downstream public water utilities, DEQ, and Cape Fear River Watch within one (1) hour of knowledge of the condition. Chemours shall

maintain a list of appropriate contacts of downstream public water utilities, which Chemours shall routinely update by requesting contact information from DEQ. Chemours shall also post a description of the condition including any estimated quantity of the release on a publicly available website within twenty-four (24) hours of knowledge of the condition.

E. COMPLIANCE MEASURES – GROUNDWATER

16. Groundwater Remediation:

a. By December 31, 2019, Chemours shall submit for approval by DEQ a complete Corrective Action Plan that complies with the requirements of the 2L Rules and guidance provided by DEQ. DEQ shall put the draft Corrective Action Plan to public notice and provide at least 30 days thereafter in which to provide written comments. DEQ shall consider any written comments received prior to approving the Corrective Action Plan.

b. Chemours shall implement the Corrective Action Plan in accordance with a schedule approved by DEQ. Except as otherwise allowed in or provided under the 2L Rules, the Corrective Action Plan must provide, upon full implementation, for the remediation of groundwater to the standards set forth in 15A NCAC 2L.0202. Subject to approval by DEQ, the Corrective Action Plan may include actions to be undertaken by other entities that have contributed to the need for such remediation.

c. The Corrective Action Plan shall include the installation of groundwater monitoring wells along Old Outfall 002, Willis Creek, Georgia Branch, and the

Cape Fear River in sufficient number and in locations adequate for monitoring the quality of groundwater entering surface waters, and include the collection and reporting of accurate baseline concentrations for all PFAS for which test methods and lab standards have been developed within each groundwater monitoring well installed pursuant to this paragraph, in addition to existing long-term wells (LTWs) along the Cape Fear River. As test methods and lab standards are developed for additional PFAS, the Corrective Action Plan shall be amended to address those PFAS.

d. At a minimum, in addition to any measures that might be otherwise required to comply with the 2L Rules, and notwithstanding any provisions of the 2L rules or other exceptions that might apply to corrective action plans, the Corrective Action Plan must require Chemours to reduce the PFAS loading to surface water (Old Outfall 002, Willis Creek, Georgia Branch, and the Cape Fear River), for the PFAS for which test methods and lab standards have been developed, by at least 75% from baseline. The baseline will be established using the average of the concentrations of the PFAS in the groundwater monitoring wells for each surface water and LTWs along the Cape Fear River over the first four (4) quarters of sampling. To demonstrate compliance, mass loading to surface water (Old Outfall 002, Willis Creek, Georgia Branch, and the Cape Fear River), must be reduced by at least 75% from baseline for at least eight (8) consecutive quarters and determined using measured concentrations in groundwater monitoring wells and LTW wells.

17. Lining of Nafion Ditch and Sedimentation Ponds: Chemours completed permanent lining of the Nafion Ditch by November 7, 2018 and permanent lining of the south sedimentation pond by November 8, 2018. Chemours completed permanent lining of the north sedimentation pond by December 31, 2018.

18. On and Offsite Assessment: Chemours shall fund a third party contractor(s), approved by DEQ after consultation with Cape Fear River Watch, to conduct a comprehensive assessment of on and offsite groundwater contamination that complies with the requirements of the 2L Rules. This assessment shall include an analysis of: (i) the source and cause of contamination; (ii) any imminent hazards to public health and safety and any actions taken to mitigate them; (iii) all receptors (to include as potential receptors drinking water wells and surface waters) and significant exposure pathways; (iv) the horizontal and vertical extent of soil and groundwater contamination and all significant factors affecting contaminant transport; and (v) geological and hydrogeological features influencing the movement, chemical, and physical character of the contaminants. This assessment shall also identify any groundwater seeps contributing to surface water contamination at the site and areas with significantly contaminated sediment. The assessment shall be submitted to DWM and Cape Fear River Watch by September 30, 2019.

F. COMPLIANCE MEASURES – REPLACEMENT DRINKING WATER SUPPLIES

19. <u>Provision of Public Water Supplies or Whole Building Filtration Systems:</u> Chemours shall establish and properly maintain permanent replacement drinking water supplies in the form of public water or a whole building filtration system for any party (i.e., household, business, school, or public building) with a private drinking water well that has been found through testing validated by DEQ to be contaminated by concentrations of GenX compounds in exceedance of 140 ng/L, or any applicable health advisory, whichever is lower. Under this provision, permanent replacement water supplies shall be established by connection to a public water supply, except that:

a. in lieu of a connection to public water supply, an affected party may elect to receive either a whole building filtration system approved by DEQ or under sink reverse osmosis systems (installed at every kitchen and bathroom sink at the election of the affected party) approved by DEQ, in which case Chemours shall install and properly maintain such filtration systems;

b. an affected party may elect to decline any permanent replacement drinking water supply;

c. if DEQ determines that connection to a public water supply to a an affected party would be cost-prohibitive (i.e., greater than $75,000) or unsafe, DEQ may authorize provision of a permanent replacement water supply to that affected party through installation and ongoing maintenance of either a whole building filtration system approved by DEQ or reverse osmosis systems approved by

DEQ installed at every kitchen and bathroom sink (at the election of the affected party).

Permanent replacement drinking water supplies established pursuant to this paragraph shall be installed no later than: (i) nine (9) months from the date Chemours becomes aware that the affected party qualifies for replacement drinking water; or (ii) if Chemours is aware that an affected party qualifies for replacement drinking water at the time this Consent Order is entered, nine (9) months from the date of entry of this Consent Order. For affected parties, Chemours shall be liable to pay for any water bills from public utilities for a period of twenty (20) years up to $75/month/affected party, provided that the monthly cap on public utility bills may be reevaluated by DEQ every two (2) years and adjusted by the average percentage increase or decrease in utility rates a given county.

20. Provision of Reverse Osmosis Drinking Water Systems: Chemours shall provide for and properly maintain permanent replacement water supplies through the installation of three under sink reverse osmosis drinking water systems approved by DEQ for any party (i.e., household, business, school, or public building) that does not qualify for permanent replacement of a private drinking water supply pursuant to paragraph 19 with a drinking water supply well contaminated by:

a. combined quantifiable concentrations of PFAS listed in **Attachment C** in exceedance of 70 ng/L; or

b. quantifiable concentrations of any individual PFAS listed in **Attachment C** in exceedance of 10 ng/L.

In the event that the water from more than one sink may be filtered using a single reverse osmosis system with the same or better results for finished water, Chemours may request approval from DEQ to implement such a system in lieu of a reverse osmosis system under each sink. For any public building (e.g., schools or government buildings) that qualifies for permanent replacement drinking water pursuant to this paragraph, Chemours shall either (i) provide and properly maintain under sink reverse osmosis drinking water systems approved by DEQ at each drinking fountain and at each sink that is used for drinking water, or (ii) provide, after consultation between DEQ, Chemours, and the management of the school or building, and subject to DEQ's approval, another effective system or equipment (such as, without limitation, construction of a deeper well, installation of a whole building filtration system, provision and supply of drinking water coolers). Permanent replacement drinking water supplies established pursuant to this paragraph shall be installed by Chemours by no later than: (i) six (6) months from the date Chemours becomes aware that an affected party qualifies for replacement drinking water; or (ii) if Chemours is aware that an affected party qualifies for replacement of drinking water at the time this Consent Order is entered, six (6) months from the date of entry of this Consent Order.

21. Private Well Testing: Chemours shall fund sampling by a third party laboratory approved by DEQ of drinking water wells for a distance of at least one-quarter (1/4) mile beyond the nearest well with test results showing a quantifiable level of any PFAS listed in **Attachment C** above 10 ng/L. Such testing shall be completed within eighteen (18) months of entry of this Order. Additionally, by December 31, 2018, Chemours shall fund re-analysis by a third party laboratory approved by DEQ for all PFAS listed in **Attachment C** of any previously collected

groundwater samples that were analyzed only for GenX, GenX Compounds, or a subset of the PFAS listed in **Attachment C**. Chemours shall retest annually to determine the extent of PFAS contamination. Chemours shall request incorporation of a plan to carry out this requirement in its Corrective Action Plan.

22. Provision of Sampling Results: On an ongoing basis and within seven (7) days of receiving any groundwater or finished water sampling results, Chemours shall provide these results to DEQ, with samples identified by both address and sample ID. Within seven (7) days of receiving test results, Chemours shall also provide sampling results to parties who have had their wells or finished water tested. For parties whose wells were tested prior to the lodging of this Consent Order, Chemours shall ensure that they have received sampling results within seven (7) days of the lodging of this Consent Order.

23. Interim Replacement of Private Drinking Water Supplies: Within three (3) days of Chemours becoming aware that a party qualifies for permanent replacement of private drinking water pursuant to paragraph 19 or 20 (or, for parties whose wells were previously tested and found to qualify for permanent replacement water pursuant to paragraph 19 or 20, as soon as practicable and no later than thirty (30) days after entry of this Consent Order), Chemours shall offer temporary replacement water supplies (i.e., bottled water) until such time as permanent replacement water supplies have been provided. For any party that is eligible for permanent replacement water supplies pursuant to paragraph 19 or 20 but declines to receive such permanent replacement water supplies, Chemours shall provide bottled water for at least three (3) months

after receiving written confirmation that an affected party declines to receive permanent replacement water supplies.

24. Drinking Water Compliance Plan:

a. By no later than sixty (60) days after entry of this Order, Chemours shall submit a plan for compliance with paragraphs 19-23 to DEQ for approval. This plan shall include a detailed schedule with milestones for Chemours to fund a third party to (1) sample private drinking water wells, (2) flush the drinking water supply plumbing (including flushing hot water heaters to remove solids) and replace, when deemed necessary by DEQ, previously installed water treatment systems (such as water softeners or filters) for any building receiving permanent replacement drinking water supplies under paragraph 19, (3) implement a testing program of finished water, as acceptable to DEQ, to demonstrate the effectiveness of filter systems, and (4) maintain filtration systems installed pursuant to paragraph 19 or 20 for a minimum of 20 years or until such a time as testing of groundwater demonstrates that each PFAS listed in **Attachment C** is below any applicable health advisory, whichever is longer.

b. DEQ shall establish a process for addressing citizen complaints related to implementation of the plan.

c. In the event that a filtration system does not function properly or effectively as determined by DEQ, Chemours shall, within 30 days, submit a plan and schedule to DEQ for providing an alternative source of drinking water. Chemours shall implement the plan upon approval by DEQ.

25. Extension of Deadlines: For good cause shown, Chemours may submit to DEQ one or more requests for extensions of up three months each for any deadline specified in paragraphs 19-24.

G. OTHER COMPLIANCE MEASURES

25.1 Split Samples: Whenever Chemours collects any water sample pursuant to this Consent Order, it shall, if DEQ so requests for that sample, send a split sample to DEQ at a location to be specified by DEQ in its request, for additional analysis. DEQ retains its authority to take independent samples and to observe any sampling taken by Chemours or Chemours' contractor(s).

26. Total Organic Fluorine: Chemours shall fund development by a third party contractor(s) of a sampling and analytical methodology for the measurement of Total Organic Fluorine in its process air emissions and process wastewater. Chemours' contractor(s) shall (i) be approved by DEQ, (ii) submit quarterly reports to DEQ, and (iii) submit the completed methodology to DEQ for review by December 31, 2020.

27. Fate and Transport: Chemours shall fund development by a third party contractor(s) of a study, based on the best available data and information, analyzing the fate and transport of identified PFAS originating from the Facility in air, surface water and groundwater. Chemours' contractor(s) shall (i) be approved by DEQ, and (ii) submit the completed study to

DEQ for review by June 30, 2019. This study may be done as part of another study required by this Order.

28. Reporting: Chemours shall submit quarterly progress reports to DEQ detailing the work and activities undertaken and completed pursuant to the requirements set forth in this Order. The quarterly reports are due no later than the thirtieth (30th) day of January, April, July, and October for the duration of this Order.

H. COMPLIANCE MEASURES-PUBLIC INFORMATION

29. Whenever Chemours proposes to make a change to its facility operations that would result in (i) the use, production, or release into the environment of a previously undisclosed PFAS or (ii) the material increase in the release to the environment of a previously disclosed PFAS, Chemours shall conduct at least one public meeting in Bladen County or, at the request of DEQ, two public meetings—one in Bladen County and one in another county down river from the Facility—and, at least four weeks prior to the meetings, notify DEQ and Cape Fear River Watch when and where the meetings will occur. Chemours shall notify the public at least two weeks before the public hearing by issuing a press release and posting the release on a publicly available website. Any meeting shall be held prior to permit applications for the change, if any, being submitted to DEQ.

30. Chemours shall post all submissions made by Chemours to DEQ pursuant to this Order, other than any submissions containing (i) confidential business information of Chemours, (ii) information concerning specific residents or other individuals, or (iii) other information that

DEQ determines would be exempt from disclosure under the North Carolina Public Records Act and should not be posted, to a publicly accessible website within 30 days of submission.

I. PENALTIES AND INVESTIGATIVE COSTS

31. Stipulated Penalties: Unless excused under paragraph 32, Chemours shall pay, by certified check payable to the North Carolina Department of Environmental Quality, stipulated penalties according to the following schedule for failure to perform activities described in paragraphs 7-30.

Failure to meet 82% emissions reduction milestone in paragraph 8	$200,000
Failure to meet 92% emissions reduction milestone in paragraph 8	$350,000
Failure to meet 99% emissions reduction milestone in paragraph 8	$1,000,000
Failure to meet technology milestone in paragraph 7 (not including control efficiency requirements).	$5,000/day for first 14 days; $30,000/day thereafter
Failure to meet any control efficiency requirements in paragraph 7.	$50,000 for the first failed test. $25,000/week thereafter until the date of testing showing compliance.
Failure to meet PFAS loading reductions incorporated pursuant to paragraph 12.	To be incorporated in amended Order pursuant to paragraph 12
Failure to meet any other deadline in this Consent Order to which no other stipulated penalties are applicable.	$1,000/day for first 7 days; $2,000/day thereafter

32. Force Majeure: The stipulated penalties specified in paragraph 31 are not due if Chemours satisfies DEQ that noncompliance was caused solely by:

a. An act of God;

b. An act of war;

c. An intentional act or omission of a third party, but this defense shall not be available if the act or omission is that of an employee or agent of Chemours or if the act or omission occurs in connection with a contractual relationship with Chemours;

d. An extraordinary event beyond the Chemours' control, specifically including any court order staying the effectiveness of any necessary permit or approval. Contractor delays or failure to obtain funding will not be considered as events beyond Chemours' control; or

e. Any combination of the above causes.

33. Civil Penalty and Investigative Costs: By no later than thirty (30) days following entry of this Order, Chemours shall pay, by certified check payable to the North Carolina Department of Environmental Quality, a civil penalty in the amount of $12,000,000 and investigative costs in the amount of $1,000,000.

J. RELEASE AND RESERVATION OF RIGHTS

34. Subject to paragraph 35, this Consent Order releases and resolves civil and administrative claims for injunctive relief and civil penalties by Plaintiff against Chemours relating to the release of PFAS from the Facility that have been or could have been brought based on information known to DEQ prior to the lodging of the original Proposed Consent Order on November 28, 2018 for past and continuing violations of the following statutes and regulations:

the Clean Water Act and regulations promulgated thereunder; the Clean Air Act and regulations promulgated thereunder; and the North Carolina statutes and regulations referenced in the Complaint, the Amended Complaint and the NOVs (collectively, the "Subject Statutes and Regulations"). Furthermore, DEQ agrees that, based on information known to DEQ prior to the lodging of the original Proposed Consent Order on November 28, 2018, this Consent Order addresses and resolves any violation or condition at the Facility insofar as it could serve as the basis for a claim, proceeding, or action pursuant to Section 13.1(a) or (c) of North Carolina Session Law 2018-5.

35. Plaintiff reserves all legal and equitable remedies available to enforce the provisions of this Consent Order, including requesting the Court to exercise its contempt powers, provided that the stipulated penalties set forth in paragraph 31 shall be the exclusive monetary remedy for any violation of this Consent Order to which they apply. Plaintiff retains all legal and equitable remedies to address any imminent and substantial endangerment to the public health or welfare or the environment arising as a result of activities at the Facility whether related to the violations addressed in this Consent Order or otherwise. Nothing in this Order shall prevent Plaintiff, acting pursuant to applicable law, from requiring Chemours to take further interim measures to reduce air emissions of PFAS other than GenX Compounds prior to installation of the thermal oxidizer. Nothing in this Consent Order shall restrict the right of DEQ to inspect or take enforcement action against Chemours for any new or subsequent violations (violations not addressed in paragraph 34) of the Subject Statutes and Regulations, or the right of Chemours to

contest any subsequent enforcement action based on allegations of new, subsequent or repeated violations, to the extent provided by law.

35.1 Nothing in this Consent Order releases any other entity, including DuPont, from any liability they may have resulting from their actions.

36. Nothing in this Consent Order releases Chemours from any liability it may have to any third parties arising from Chemours' actions or releases any claims by any third party, including the claims in: (a) Nix v. The Chemours Co. FC, LLC, No. 7:17-CV-0189-D (E.D.N.C.); (b) Cape Fear Public Utility Authority v. The Chemours Co. FC, LLC, No. 7:17-CV-00195-D (E.D.N.C.); (c) Morton v. The Chemours Co., No. 7:17-CV-00197-D (E.D.N.C.); (d) Carey v. E.I. du Pont de Nemours & Co., No. 7:17-CV-00201-D (E.D.N.C.); (d) Brunswick Co. v. DowDuPont, Inc., No. 7:17-CV-00209-D (E.D.N.C.) (including the claims asserted by Town of Wrightsville Beach and Lower Cape Fear Water and Sewer Authority in the Master Complaint of Public Water Suppliers filed January 31, 2018); and (e) Dew v. E.I. du Pont de Nemours & Co., No. 7:18-cv-00073-D (E.D.N.C.).

K. INTERVENTION OF CAPE FEAR RIVER WATCH

37. For the purpose of entering into this Consent Order and resolving Cape Fear River Watch's pending actions in Cape Fear River Watch v. North Carolina Department of Environmental Quality, 18 CVS 2462 (New Hanover Cty. Sup. Ct.) and Cape Fear River Watch v. Chemours Company FC, LLC, No. 7:18-cv-00159 (E.D.N.C.), Plaintiff and Chemours consent to the intervention of Cape Fear River Watch as a Plaintiff in this matter.

38. Plaintiff shall have sole authority to enforce of the requirements of this Consent Order in this Court against Chemours, except that Cape Fear River Watch shall also have authority to enforce paragraphs 7, 8, 10, 11, 11.1, 11.2, 12, 15, 16(d), 29, 40, and 46, provided that Cape Fear River Watch's authority to enforce a requirement under paragraph 7 or 8 shall cease upon incorporation of that requirement into the Facility's air permit, and further provided that Cape Fear River Watch shall provide Chemours and DEQ with at least 14 days advance notice of any compliance concern that could result in an enforcement action, and the parties shall confer in an effort to resolve any dispute prior to its presentation to the Court. Furthermore, Cape Fear River Watch shall have the right to be heard in any proceeding before this Court in which Plaintiff is seeking to have the terms of this Consent Order enforced.

39. Within fifteen (15) days of entry of this Consent Order, Cape Fear River Watch agrees to voluntarily dismiss with prejudice its Petition for Judicial Review in Cape Fear River Watch v. North Carolina Department of Environmental Quality, 18 CVS 2462 (New Hanover Cty. Sup. Ct.). Within sixty (60) days of entry of this Consent Order, Cape Fear River Watch agrees to voluntarily dismiss with prejudice its action in Cape Fear River Watch v. Chemours Company FC, LLC, No. 7:18-cv-00159 (E.D.N.C.) for Chemours' alleged violations of the Clean Water Act and the Toxic Substances Control Act alleged by the Cape Fear River Watch prior to the date of entry of this Order.

40. Chemours shall provide quarterly progress reports submitted to DEQ concurrently to Cape Fear River Watch. Within thirty (30) days of receiving those reports, DEQ shall make relevant staff available for an in person meeting with Cape Fear River Watch to discuss the status

of Chemours' performance of its obligations under the Consent Order and DEQ's review of any relevant submissions.

L. MISCELLANEOUS

41. Effect of this Order: This Consent Order (a) shall be binding on the parties as an order of the Court, (b) is not, and shall not be construed to be, a permit issued pursuant to any federal or state statute or regulation, and (c) is not, and shall not be construed to be, a determination on the merits of any of the factual allegations or legal claims advanced by any party in this action, including in DEQ's Complaint or Amended Complaint, Chemours' Answer, any Notices of Violation, or the proposed findings of fact or conclusions of law filed by DEQ in connection with prior motions or status reports. Nothing in this Consent Order limits Chemours' obligations to comply with the requirements of all applicable state and federal laws and regulations, provided that nothing in this sentence limits the scope of the release under paragraph 34.

42. No Admission: By agreeing to entry of this Consent Order, Chemours makes no admission of law or fact with respect to the allegations in the Complaint or Amended Complaint, any Notices of Violation, or the proposed findings of fact or conclusions of law filed by DEQ in connection with prior motions or status reports, and does not admit to any other factual or legal determination, and denies any non-compliance or violation of any law, regulation or permit referenced therein or in this Consent Order. In particular, and without limiting the foregoing, Chemours does not admit that any concentration-based standard referenced herein for GenX compounds or other PFAS is scientifically supported or legally or factually appropriate.

43. Findings of Fact and Conclusions of Law: The Parties waive any requirement for formal findings of fact and conclusions of law and agree that this Consent Order shall be binding upon them the same as if entered by a Superior Court Judge after a hearing on the merits of all matters now pending.

44. Carbon Filtration Systems: DEQ and Chemours have cooperated to develop and implement a program for testing the efficacy of granular activated carbon filtration systems in removing GenX and PFAS compounds from drinking water. Under test conditions, PFAS tested in post-treatment water were either not detected at all or detected at concentrations below 10 ng/L and near the reporting limit.

45. Cooperation: The Parties acknowledge that this Consent Order is the product of good faith efforts and discussions since the filing of the draft Proposed Order, and that Chemours has cooperated with DEQ in responding to issues and requests raised by DEQ and in voluntarily undertaking significant corrective and remedial measures while these discussions were ongoing.

46. Notices and Submissions:

a. Whenever notice is required to be given or a document is required to be sent by one Party to another under the terms of this Consent Order, it shall be provided to all parties, directed to the individuals at the addresses specified below, unless those individuals or their successors give notice of a change to the other Parties in writing. Notice or submission by electronic mail is acceptable.

As to DEQ:

Sheila Holman

Assistant Secretary for the Environment
1601 Mail Service Center
Raleigh, NC 27699-1601
sheila.holman@ncdenr.gov

b. Chemours shall provide all submissions and notices made by Chemours to DEQ, DAQ, DWM, DWR pursuant to this Order concurrently to Cape Fear River Watch, redacting confidential business information of Chemours, and information concerning specific residents or other individuals. DEQ shall consider all timely comments received from Cape Fear River Watch prior to agency approval of any such document.

47. Permits: In accordance with applicable law, DEQ agrees to review and act timely on all applications by Chemours for permits necessary for Chemours to undertake the actions required under this Consent Order, including without limitation all permits necessary for Chemours to construct, install and operate the thermal oxidizer system. In accordance with applicable law, DEQ agrees (i) to review and act timely on an application by Chemours for a new NPDES permit; (ii) to meet monthly with Chemours and work in good faith with Chemours to identify, review and discuss information necessary for Chemours to complete its application; and (iii) to review and act on Chemours' application in a manner consistent with the Clean Water Act and associated regulations as well as N.C. Gen. Stat. § 143-215.1 and associated regulations, practices, and procedures for permitting the discharge of industrial process wastewater with conditions and limitations necessary to protect public health and the environment.

48. Public Participation: The original Proposed Consent Order was previously released for public notice and comment by DEQ for a period of forty seven (47) days. DEQ reserved the right to withdraw or withhold its consent if the comments regarding the Consent Order disclosed facts or considerations indicating that the Consent Order is inappropriate, improper, inadequate, or required modification. Following the close of that comment period and DEQ's consideration of comments received, (i) DEQ fully addressed the comments it received, (ii) the Parties agreed to the modifications that are reflected in this Consent Order in response to public comment, and (iii) the Parties support and will seek the entry of this Consent Order by the Court. The Parties consent

to entry of this Consent Order and agree not to withdraw from or oppose entry of this Consent Order by the Court or to challenge any provision of the Consent Order.

49. Successors and Assigns: This Consent Order shall be binding upon, and inure to the benefit of, the Parties and their respective successors and assigns (who shall not be considered third parties). No third party shall be deemed the beneficiary of, or as having the right to enforce, this Consent Order.

50. Effective Date: This Consent Order shall become effective on the date that it is entered by the Court. In the event that deadlines for any obligations under this Consent Order arise prior to its entry by the Court, such obligations shall take effect upon such entry by the Court.

51. Duration: This Court retains jurisdiction over both the subject matter of this Consent Order and the Parties for the duration of the performance of the terms and provisions of this Consent Order to effectuate or enforce compliance with the terms of this Consent Order, provided that after January 1, 2023, any provision of this Consent Order may be terminated under the following circumstances:

a. (i) Chemours has discharged the obligations set forth in the provision and six months have elapsed since the date on which Chemours discharged its obligations; or (ii) If the requirements of the provision have not been fully discharged, requirements at least as stringent have been incorporated into a permit, Corrective Action Plan, or other regulatory instrument enforceable by DEQ; and

b. (i) The Parties stipulate that the above conditions have been met and file a notice of full or partial termination with the Court; or (ii) After all parties have been heard, Chemours demonstrates to the Court that the conditions specified in subparagraph (a) above have been met.

52. This Consent Order may be signed out-of-court, out-of-term, and out-of-county.

This the 25th day of February, 2019.

Douglas B. Sasser
Superior Court Judge

Old Outfall No. 2- Treatment Options
Focused Feasability Study Report - PFAS
Chemours Fayetteville Works
Fayetteville, North Carolina

Attachment A

Drawn:	Date:	File Project Number:
C. Oneal	3/26/2018	449338.01050
Revision: 1	Figure Number: 5	
Name: Option_F4		

Path: D:\GIS\Fayetteville\Gis\Project_figures\2018\Option_F4.mxd

ATTACHMENT B

Chemours' proposed plan to conduct toxicity studies pursuant to paragraph 14 shall include:

(i) Testing of the following PFAS compounds:*

<table>
<tr><th colspan="2">Common Name</th><th colspan="2">Chemical Name</th><th colspan="2">CASN</th><th>Chemical Formula</th></tr>
<tr><td colspan="2">PFMOAA</td><td colspan="2">Perfluoro- 2-methoxyacetic acid</td><td colspan="2">674-13-5</td><td>C3HF5O3</td></tr>
<tr><td>PMPA</td><td>PFMOPrA</td><td>Perfluoro-2-methoxypropanoic acid</td><td>Perfluoro-3-methoxypropanoic acid</td><td>13140-29-9</td><td>377-73-1</td><td>C4HF7O3</td></tr>
<tr><td colspan="2">PFO2HXA</td><td colspan="2">Perfluoro(3,5-dioxahexanoic) acid</td><td colspan="2">39492-88-1</td><td>C4HF7O4</td></tr>
<tr><td>PEPA</td><td>PFMOBA</td><td>2,3,3,3-Tetrafluoro-2-(pentafluoroethoxy) propanoic acid</td><td>Perfluoro-4-methoxybutanoic acid</td><td>267239-61-2</td><td>863090-89-5</td><td>C5HF9O3</td></tr>
<tr><td colspan="2">PFESA-BP2 / Nafion BP #2</td><td colspan="2">Nafion Byproduct 2</td><td colspan="2">749836-20-2</td><td>C7H2F14O5S</td></tr>
</table>

* For clarification, compounds identified with two common names in Attachment B or C shall be tested using a single CASN, to be proposed by Chemours and approved by DEQ.

(ii) The following studies, which shall be conducted following applicable USEPA, OECD protocols as defined in the USEPA TSCA, OPPT or other appropriate programs as determined by DEQ:

a. Toxicity Studies:
- 28-day oral immunotoxicity study in rats
- 28-day oral immunotoxicity study in mice
- 90-day repeated dose oral toxicity study in rats
- 90-day repeated dose oral toxicity study in mice

b. Ecological Toxicity Studies:
- Algal acute (72-hour growth) toxicity study
- Daphnid acute toxicity study
- Daphnid chronic (reproduction) toxicity study
- Fish acute toxicity study
- Sediment 10-day freshwater invertebrates toxicity test

(iii) A detailed proposed schedule of work.

ATTACHMENT C

For purposes of paragraphs 19-21 and 24 "PFAS" shall mean the following compounds, unless Chemours demonstrates to the reasonable satisfaction of DEQ that the PFAS in a given well did not originate from the Facility:

<table>
<tr><th colspan="2">Common Name</th><th colspan="2">Chemical Name</th><th colspan="2">CASN</th><th>Chemical Formula</th></tr>
<tr><td colspan="2">PFMOAA</td><td colspan="2">Perfluoro- 2-methoxyacetic acid</td><td colspan="2">674-13-5</td><td>C3HF5O3</td></tr>
<tr><td>PMPA</td><td>PFMOPrA</td><td>Perfluoro-2-methoxypropanoic acid</td><td>Perfluoro-3-methoxypropanoic acid</td><td>13140-29-9</td><td>377-73-1</td><td>C4HF7O3</td></tr>
<tr><td colspan="2">PFO2HXA</td><td colspan="2">Perfluoro(3,5-dioxahexanoic) acid</td><td colspan="2">39492-88-1</td><td>C4HF7O4</td></tr>
<tr><td>PEPA</td><td>PFMOBA</td><td>2,3,3,3-Tetrafluoro-2-(pentafluoroethoxy) propanoic acid</td><td>Perfluoro-4-methoxybutanoic acid</td><td>267239-61-2</td><td>863090-89-5</td><td>C5HF9O3</td></tr>
<tr><td colspan="2">PFO3OA</td><td colspan="2">Perfluoro(3,5,7-trioxaoctanoic) acid</td><td colspan="2">39492-89-2</td><td>C5HF9O5</td></tr>
<tr><td colspan="2">PFO4DA</td><td colspan="2">Perfluoro(3,5,7,9-tetraoxadecanoic) acid</td><td colspan="2">39492-90-5</td><td>C6HF11O6</td></tr>

Definitions:
[1] Exposure Units (EUs) are defined as follows:
EU1 - 2.5 kilometer radius, northeast
EU2 - 2.5 kilometer radius, southeast
EU3 - 2.5 kilometer radius, southwest
EU4 - 2.5 kilometer radius, northwest
EU5 - 5 kilometer radius, northeast
EU6 - 5 kilometer radius, southeast
EU7 - 5 kilometer radius, southwest
EU8 - 5 kilometer radius, northwest
EU9 - 10 kilometer radius, northeast
EU10 - 10 kilometer radius, southeast
EU11 - 10 kilometer radius, southwest
EU12 - 10 kilometer radius, northwest
[2] Surface soil (0-0.5 ft bgs) results represent composite samples. Subsurface soil (4-4.5 ft bgs) results represent discrete samples
[3] The higher of the duplicate and parent result was used in the SLEA intake and risk characterization

Notes:
Bold - Analyte detected above associated reporting limit
< - Analyte not detected above associated reporting limit.
"--" - Data not available
ft bgs = feet below ground surface
J - Analyte detected. Reported value may not be accurate or precise
ng/kg - nanogram(s) per kilogram
DUP - field duplicate sample
R - Result rejected based on quality assurance/quality control criteria
UJ – Analyte not detected. Reporting limit may not be accurate or precise.

Definitions:
[1] Exposure Units (EUs) are defined as follows:

EU5 - 5 kilometer radius, northeast
EU6 - 5 kilometer radius, southeast
EU7 - 5 kilometer radius, southwest
EU8 - 5 kilometer radius, northwest
EU9 - 10 kilometer radius, northeast
EU10 - 10 kilometer radius, southeast
EU11 - 10 kilometer radius, southwest
EU12 - 10 kilometer radius, northwest

[2] The analytical results presented in the table represent the maximum concentration reported within the sampling date range. Not all maximums co-occurred such that the sum of maximums at each location is an "artificial composite sample
[3] Reporting limits for a limited number of samples with non-detect HFPO-DA results were not available (shown as "0" in the table); these samples were excluded from the statistical summary calculations.

Notes:
Bold - Analyte detected above associated reporting limit
< - Analyte not detected above associated reporting limit.
"--" - Data not available
ng/L - nanogram(s) per liter

Notes
[1] Exposure Units (EUs) are defined as follows:
EU13 - Upstream Cape Fear River
EU14 - Site-Adjacent Cape Fear River
EU16 - 8 Miles Downstream, Cape Fear River (Bladen Bluffs)
EU17 - 55 Miles Downstream Cape Fear River (Kings Bluffs)
EU18 - Onsite Pond 1
EU19 - Offsite Pond B
[2] https://www.ncwater.org/basins/Cape_Fear/GenXDataspreadsheet.pdf
[3] Data were provided by the Cape Fear Public Utility Authority.

Definitions:
Bold - Analyte detected above associated reporting limit
< - Analyte not detected above associated reporting limit
-- - No data reported
J - Analyte detected. Reported value may not be accurate or precise
UJ – Analyte not detected. Reporting limit may not be accurate or precise.
ng/L - nanogram(s) per liter

Notes

[1] Exposure Units are defined as follows:
- EU13 - Upstream Cape Fear River
- EU14 - Site-Adjacent Cape Fear River
- EU15 - 4 Miles Downstream, Cape Fear River
- EU16 - 8 Miles Downstream, Cape Fear River (Bladen Bluffs)
- EU18 - Onsite Pond 1

[2] Sample IDs use the following abbreviations to indicate fish species. Only fillet samples were evaluated in the human health SLEA.
- LMB - Largemouth Bass
- BC - Blue Catfish
- CC - Channel Catfish
- FH - Flathead Catfish
- Redbreast - Redbreasted Sunfish

[3] Field staff mistakenly labeled samples collected from CFR-06 as location CFR-05. Coordinates confirmed CFR-06 was correct.
[4] Field staff mistakenly labeled samples collected from CFR-07 as location CFR-06. Coordinates confirmed CFR-07 was correct.

Definitions:
Bold - Analyte detected above associated reporting limit
< - Analyte not detected above associated reporting limit
-- - No data reported
J - Analyte detected. Reported value may not be accurate or precise
UJ – Analyte not detected. Reporting limit may not be accurate or precise.
ng/kg - nanogram(s) per kilogram
mm - millimeters

Notes

[1] Exposure Units are defined as follows:
- EU13 - Upstream Cape Fear River
- EU14 - Site-Adjacent Cape Fear River
- EU15 - 4 Miles Downstream, Cape Fear River
- EU16 - 8 Miles Downstream, Cape Fear River (Bladen Bluffs)
- EU18 - Onsite Pond 1

[2] Sample IDs use the following abbreviations to indicate fish species. Only fillet samples were evaluated in the human health SLEA.
- LMB - Largemouth Bass
- BC - Blue Catfish
- CC - Channel Catfish
- FH - Flathead Catfish
- Redbreast - Redbreasted Sunfish

[3] Field staff mistakenly labeled samples collected from CFR-06 as location CFR-05. Coordinates confirmed CFR-06 was correct.
[4] Field staff mistakenly labeled samples collected from CFR-07 as location CFR-06. Coordinates confirmed CFR-07 was correct.

Definitions:
Bold - Analyte detected above associated reporting limit
< - Analyte not detected above associated reporting limit
-- - No data reported
J - Analyte detected. Reported value may not be accurate or precise
UJ – Analyte not detected. Reporting limit may not be accurate or precise.
ng/kg - nanogram(s) per kilogram
mm - millimeters

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	664.2

Nonparametric Distribution Free UCL Statistics

Data do not follow a Discernible Distribution at 5% Significance Level

Suggested UCL to Use

95% KM (Chebyshev) UCL 1411

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

DW_EU1_PEPA

General Statistics

Total Number of Observations	6	Number of Distinct Observations	4
Number of Detects	4	Number of Non-Detects	2
Number of Distinct Detects	3	Number of Distinct Non-Detects	1
Minimum Detect	370	Minimum Non-Detect	20
Maximum Detect	820	Maximum Non-Detect	20
Variance Detects	48600	Percent Non-Detects	33.33%
Mean Detects	490	SD Detects	220.5
Median Detects	385	CV Detects	0.45
Skewness Detects	1.976	Kurtosis Detects	3.914
Mean of Logged Detects	6.132	SD of Logged Detects	0.387

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.
For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test on Detects Only

DW_EU1_PFECA-G

General Statistics

Total Number of Observations	6	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	6
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU1_PFECA-G was not processed!

DW_EU1_PFESA-BP1

General Statistics

Total Number of Observations	6	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	6
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU1_PFESA-BP1 was not processed!

DW_EU1_PFESA-BP2

Number of Distinct Detects	4	Number of Distinct Non-Detects	1
Minimum Detect	5	Minimum Non-Detect	2
Maximum Detect	77	Maximum Non-Detect	2
Variance Detects	907	Percent Non-Detects	33.33%
Mean Detects	35.5	SD Detects	30.12
Median Detects	30	CV Detects	0.848
Skewness Detects	1.041	Kurtosis Detects	2.039
Mean of Logged Detects	3.188	SD of Logged Detects	1.144

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use
guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.
For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test on Detects Only

Suggested UCL to Use

95% KM Bootstrap t UCL	N/A	95% Hall's Bootstrap	421272

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
Number of Detects	1	Number of Non-Detects	2
Number of Distinct Detects	1	Number of Distinct Non-Detects	2

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!
It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU3_PFO3OA was not processed!

DW_EU3_PFO4DA

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
Number of Detects	1	Number of Non-Detects	2
Number of Distinct Detects	1	Number of Distinct Non-Detects	2

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!
It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU3_PFO4DA was not processed!

DW_EU3_PFO5DA

General Statistics

Total Number of Observations	3	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	3
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU3_PFO5DA was not processed!

DW_EU3_PMPA

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	0
Minimum	310	Mean	1010
Maximum	1800	Median	920
SD	749.1	Std. Error of Mean	432.5
Coefficient of Variation	0.742	Skewness	0.533

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use
guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.
For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL	19.72

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL 412.5

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU5_PFESA-BP1 was not processed!

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL 33.31

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

Suggested UCL to Use

95% KM Approximate Gamma UCL	304.2

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

General Statistics

Total Number of Observations	47	Number of Distinct Observations	4
Number of Detects	0	Number of Non-Detects	47
Number of Distinct Detects	0	Number of Distinct Non-Detects	4

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU7_PFO5DA was not processed!

General Statistics

Total Number of Observations	208	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	208
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU8_PFECA-G was not processed!

DW_EU8_PFESA-BP1

General Statistics

Total Number of Observations	214	Number of Distinct Observations	14
Number of Detects	1	Number of Non-Detects	213
Number of Distinct Detects	1	Number of Distinct Non-Detects	13

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!
It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU8_PFESA-BP1 was not processed!

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

General Statistics

Total Number of Observations	208	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	208
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable DW_EU8_PFO5DA was not processed!

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

DL/2 is not a recommended method, provided for comparisons and historical reasons

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

Suggested UCL to Use

95% KM Approximate Gamma UCL	49.68

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Theta hat (MLE)	25.12	Theta star (bias corrected MLE)	28.04
nu hat (MLE)	83.9	nu star (bias corrected)	75.17
Mean (detects)	42.16		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	20.74

Maximum	200	Median	12
